## 1. INTRODUCTION

Let

$$
\mathrm{F}_{0}=0, \quad \mathrm{~F}_{1}=1, \quad \mathrm{~F}_{\mathrm{n}+1}=\mathrm{F}_{\mathrm{n}}+\mathrm{F}_{\mathrm{n}-1} \quad(\mathrm{n} \geq 1)
$$

It is well known that every positive integer N can be uniquely represented in the form

$$
\begin{equation*}
\mathrm{N}=\mathrm{F}_{\mathrm{k}_{1}}+\mathrm{F}_{\mathrm{k}_{2}}+\mathrm{F}_{\mathrm{k}_{3}}+\cdots, \tag{1.1}
\end{equation*}
$$

where

$$
\begin{equation*}
k_{1} \geq 2, \quad k_{i+1}-k_{i} \geq 2 \quad(i=1,2,3, \cdots) ; \tag{1.2}
\end{equation*}
$$

Equation (1.1) is called the canonical representation of $N$. Let $A_{k}$ denote the set of positive integers N with $\mathrm{k}_{1}=\mathrm{k}$ in (1.1). It was proved in [2] that

$$
\begin{array}{ll}
A_{2 t}=a b^{t-1} a(\mathbb{N}) & (t=1,2,3, \cdots),  \tag{1.3}\\
A_{2 t+1}=b^{t} a(\mathbb{N}) & (t=1,2,3, \cdots),
\end{array}
$$

where denotes the set of positive integers and the functions $a(n), b(n)$ are defined by means of

$$
\begin{equation*}
\mathrm{a}(\mathrm{n})=[\alpha \mathrm{n}], \quad \mathrm{b}(\mathrm{n})=\left[\alpha^{2} \mathrm{n}\right], \quad \alpha=\frac{1}{2}(1+\sqrt{5}), \tag{1.5}
\end{equation*}
$$

[^0]and $[x]$ denotes the greatest integer $\leq x$. In the paper cited, considerable use is made of the function $e(N)$ defined by
\[

$$
\begin{equation*}
\mathrm{e}(\mathrm{~N})=\mathrm{F}_{\mathrm{k}_{1}-1}+\mathrm{F}_{\mathrm{k}_{2}-1}+\mathrm{F}_{\mathrm{k}_{3}-1}+\cdots ; \tag{1.6}
\end{equation*}
$$

\]

This function was introduced in an earlier paper [1].
It is natural to try to extend the results of [2] to Fibonacci numbers of higher order. For a number of reasons we limit ourselves in the present paper to the numbers defined by
(1.7) $\quad G_{0}=0, \quad G_{1}=G_{2}=1, \quad G_{n+1}=G_{n}+G_{n-1}+G_{n-2} \quad(n \geq 2)$.

To begin with, we have the unique canonical representation

$$
\begin{equation*}
\mathrm{N}=\epsilon_{2} \mathrm{G}_{2}+\epsilon_{3} \mathrm{G}_{3}+\epsilon_{4} \mathrm{G}_{4}+\cdots \tag{1.8}
\end{equation*}
$$

where each $\epsilon_{i}$ is either 0 or 1 and now

$$
\begin{equation*}
\epsilon_{i} \epsilon_{i+1} \epsilon_{i+2}=0 \quad(i=2,3,4, \cdots) \tag{1.9}
\end{equation*}
$$

Corresponding to the function $\mathrm{e}(\mathrm{N})$ defined by (1.6) we introduce the function

$$
\begin{equation*}
\mathrm{f}(\mathrm{~N})=\epsilon_{2} \mathrm{G}_{1}+\epsilon_{3} \mathrm{G}_{2}+\epsilon_{4} \mathrm{G}_{3}+\cdots \tag{1.10}
\end{equation*}
$$

Moreover if

$$
\begin{equation*}
\mathrm{N}=\epsilon_{2}^{\prime} \mathrm{G}_{2}+\epsilon_{3}^{\prime} \mathrm{G}_{3}+\epsilon_{4}^{\prime} \mathrm{G}_{4}+\cdots \tag{1.11}
\end{equation*}
$$

where each $\epsilon_{i}^{\prime}$ is either 0 or 1 , is any representation of $N$, then

$$
\mathrm{f}(\mathrm{~N})=\epsilon_{2}^{\prime} \mathrm{G}_{1}+\epsilon_{3}^{\prime} \mathrm{G}_{2}+\epsilon_{4}^{\prime} \mathrm{G}_{4}+\cdots .
$$

Let $C_{k}$ denote the set of positive integers $\{N\}$ for which $\epsilon_{k}$ is the first nonzero $\epsilon_{i}$ in (1.8). We obtain results analogous to (1.3) and (1.4), namely

$$
\begin{array}{cl}
\mathrm{C}_{3 k+2}=a c^{k} a(\mathbb{N}) \cup a c^{k} b(\mathbb{N}) & (k \geq 0), \\
C_{3 k+3}=b c^{k} a(\mathbb{N}) \cup b c^{k} b(\mathbb{N}) & (k \geq 0), \\
C_{3 k+4}=c^{k+1} a(\mathbb{N}) \cup c^{k+1} b(\mathbb{N}) & (k \geq 0) . \tag{1.14}
\end{array}
$$

The functions $a, b, c$ are defined in Section 3 below; we have been unable to find explicit formulas analogous to (1.5). We show, however, that the functions can be characterized in the following way. They are strictly monotone functions whose ranges constitute a disjoint partition of the positive integers; moreover

$$
\begin{equation*}
b(n)=a^{2}(n)+1, \quad c(n)=a(n)+b(n)+n . \tag{1.15}
\end{equation*}
$$

In addition to the canonical representation (1.8), we find it convenient to introduce a second canonical representation

$$
\begin{equation*}
N=G_{3 k+1}+\epsilon_{3 k+2} G_{3 k+2}+\cdots, \tag{1.16}
\end{equation*}
$$

where $\mathrm{k} \geq 0$ and as before

$$
\epsilon_{i} \epsilon_{i+1} \epsilon_{i+2}=0 \quad(i \geq 3 k+1)
$$

Moreover, making use of the representation (1.16),

$$
\left\{\begin{array}{l}
a(N)=G_{3 k+2}+\epsilon_{3 k+2} G_{3 k+3}+\cdots  \tag{1.17}\\
b(N)=G_{3 k+3}+\epsilon_{3 k+2} G_{3 k+4}+\cdots \\
c(N)=G_{3 k+4}+\epsilon_{3 k+2} G_{3 k+5}+\cdots
\end{array}\right.
$$

It is because of these formulas for $a(N), b(N), c(N)$ that (1.16) is particularly useful.

## 2. PRELIMINARIES

Let $\mathrm{Q}_{\mathrm{n}}$ be the set of non-negative $\mathbb{N}^{\prime}$ 's which can be written canonically in the form

$$
\begin{equation*}
\mathrm{N}=\epsilon_{2} \mathrm{G}_{2}+\epsilon_{3} \mathrm{G}_{3}+\cdots+\epsilon_{\mathrm{n}} \mathrm{G}_{\mathrm{n}} \tag{2.1}
\end{equation*}
$$

Then we have

$$
\begin{align*}
& Q_{2}=\{0,1\}, \quad Q_{3}=\{0,1,2,3\}, \\
& Q_{4}=\{0,1,2,3,4,5,6, \ldots\} \tag{2.2}
\end{align*}
$$

We can see easily by induction that $Q_{n}$ is a disjoint union:

$$
\begin{equation*}
Q_{n}+\left(Q_{n-3}+G_{n-1}+G_{n}\right) \cup\left(Q_{n-2}+G_{n}\right) \cup Q_{n-1} \tag{2.3}
\end{equation*}
$$

and that

$$
\begin{equation*}
Q_{n}=\left\{0,1,2, \cdots, G_{n+1}-1\right\} \tag{2.4}
\end{equation*}
$$

These remarks imply the following theorem.
Theorem 1. Any positive integer N can be uniquely represented in the canonical form (2.1).

Theorem 2. If N is given (not necessarily canonically) by

$$
N=\epsilon_{2}^{\prime} G_{2}+\epsilon_{3}^{\prime} G_{3}+\cdots,
$$

then

$$
\mathrm{f}(\mathrm{~N})=\epsilon_{2}^{\prime} \mathrm{G}_{1}+\epsilon_{3}^{\prime} \mathrm{G}_{2}+\cdots
$$

Proof. Given any representation $\epsilon^{\prime}=\left(\epsilon_{2}^{\prime}, \epsilon_{3}^{\prime}, \ldots\right)$ of $N$ we obtain another representation $s\left(\epsilon^{\prime}\right)$ of N by choosing, in $\epsilon$, the block of the form $(1,1,1,0)$ that is farthest right and replacing it by the block $(0,0,0,1)$. If there is no such block, $\epsilon^{\prime}$ is canonical and we set $s\left(\epsilon^{\prime}\right)=\epsilon^{\prime}$. It is clear that sufficiently many applications of $s$ will yield the canonical representation of N , but it is also clear that

$$
\begin{equation*}
\epsilon_{2}^{\prime} G_{1}+\epsilon_{3}^{\prime} G_{2}+\cdots=s\left(\epsilon^{\prime}\right)_{2} G_{1}+s\left(\epsilon^{\prime}\right)_{3} G_{2}+\cdots, \tag{2.5}
\end{equation*}
$$

establishing the theorem.
Theorem 3. We have $\mathrm{f}(\mathrm{N}+1) \geq \mathrm{f}(\mathrm{N})$, with equality if and only if $N \in C_{2}$ 。

Proof. If $\mathrm{N} \notin \mathrm{C}_{2}$ then

$$
N=\epsilon_{3} G_{3}+\epsilon_{4} G_{4}+\cdots
$$

and

$$
\mathrm{N}+1=\mathrm{G}_{2}+\epsilon_{3} \mathrm{G}_{3}+\cdots
$$

Hence

$$
\mathrm{f}(\mathrm{~N}+1)=\mathrm{G}_{1}+\epsilon_{3} \mathrm{G}_{2}+\cdots=\mathrm{f}(\mathrm{~N})+1
$$

If $N \in C_{2}$ then either
(a)

$$
N=G_{2}+G_{3}+\epsilon_{5} G_{5}+\cdots
$$

or
(b) $\quad N=G_{2}+\epsilon_{4} G_{4}+\cdots$.

In case (a)

$$
\mathrm{N}+1=\mathrm{G}_{4}+\epsilon_{5} \mathrm{G}_{5}+\ldots
$$

and

$$
\mathrm{f}(\mathrm{~N}+1)=\mathrm{G}_{\underline{p}}+\epsilon_{5} \mathrm{G}_{\underline{2}}+\cdots=\mathrm{f}(\mathrm{~N}) .
$$

In case (b)

$$
N+1=G_{3}+\epsilon_{4} G_{4}+\cdots
$$

and

$$
\mathrm{f}(\mathrm{~N}+1)=\mathrm{G}_{2}+\epsilon_{4} \mathrm{G}_{3}+\cdots=\mathrm{f}(\mathrm{~N})
$$

This completes the proof.
Theorem 4. We have $N-1 \notin C_{2}$ if and only if $N \in C_{k}$, where $k \equiv$ $2(\bmod 3)$.

Proof. If $N \in C_{2}$, there is nothing to prove, so suppose $N \in C_{k}, k$ $>2$; let N have the canonical representation

$$
\mathrm{N}=\mathrm{G}_{\mathrm{k}}+\epsilon_{\mathrm{k}+1} \mathrm{G}_{\mathrm{k}+1}+\cdots
$$

Then we have
(2.6) $\quad G_{k}=\left\{\begin{array}{l}G_{0}+G_{1}+G_{2}+\left(G_{4}+G_{5}\right)+\cdots+G_{k-2}+G_{k-1} k \equiv 0(\bmod 3) \\ G_{1}+G_{2}+G_{3}+\left(G_{5}+G_{6}\right)+\cdots+\left(G_{k-2}+G_{k-1}\right) k \equiv 1(\bmod 3) \\ G_{2}+G_{3}+G_{4}+\left(G_{6}+G_{7}\right)+\cdots+\left(G_{k-2}+G_{k-1}\right) k \equiv 2(\bmod 3) .\end{array}\right.$

Thus we see that only in the case $k \equiv 2(\bmod 3)$ we have $G_{k}-1 \notin C_{2}$.
Theorem 5. The following identities hold for $\mathrm{k}>2$.
(2.7)

$$
f\left(G_{k}-1\right)= \begin{cases}G_{k-1} & k \equiv 0(\bmod 3) \\ G_{k-1} & k \equiv 1(\bmod 3) \\ G_{k-1}-1 & k \equiv 2(\bmod 3)\end{cases}
$$

Proof. Making use of (2.6), we readily get (2.7).
3. THE FUNCTIONS $a, b$, AND $c$

In this section we define three strictly monotone functions on the positive integers, which we display as an array:

$R:$| 1 | 2 | 3 | 4 | 5 |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $a(1)$ | $a(2)$ | $a(3)$ | $a(4)$ | $a(5)$ | $\ldots$ |
| $b(1)$ | $b(2)$ | $b(3)$ | $b(4)$ | $b(5)$ | $\ldots$ |
| $c(1)$ | $c(2)$ | $c(3)$ | $c(4)$ | $c(5)$ | $\ldots$ |

We begin by setting $a(1)=1, \quad b(1)=2, \quad c(1)=4, \quad a(2)=3$, and fill the rest of the array by induction. Suppose that columns 1 to $n$ have been filled, and also that $a(n+1)$ is known. Then we fill row a to column $a(n+1)$ in increasing order with the first integers that have not appeared so far in the array. Then we let $b(n+1)$ be the next integer that has not appeared, and we set

$$
c(n+1)=n+1+a(n+1)+b(n+1)
$$

Thus we get

R: | n | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| :---: | :---: | ---: | ---: | ---: | ---: | :---: | :---: | :---: | :---: | :---: |
| a | 1 | 3 | 5 | 7 | 8 | 10 | 12 | 14 | 16 | 18 |
| b | 2 | 6 | 9 | 13 | 15 | 19 | 22 | 26 | 30 |  |
| c | 4 | 11 | 17 | 24 | 28 | 35 | 41 | 48 | 55 |  |

It is clear from the definition of $R$ that the ranges $a(N), b(N)$, and $c(N)$ are disjoint and exhaust the positive integers. We will now establish several relations between $a, b$ and $c$.

Theorem 6. For every positive integer N, the following identities hold:

$$
\begin{equation*}
c(N)=a(N)+b(N)+N \tag{3.3}
\end{equation*}
$$

$$
\begin{equation*}
\mathrm{c}(\mathrm{~N})=\mathrm{ab}(\mathrm{~N})+1=\mathrm{ba}(\mathrm{~N})+2 \tag{3.6}
\end{equation*}
$$

Proof. 1. ((3.3)) This is the definition of $c(N)$.
2. ((3.4)) Let $N$ be the first integer for which (3.4) fails. Then we must have, for some $K<N$,

$$
c(K)=a^{2}(N)+1 \quad \text { and } \quad b(N)-a^{2}(N)+2
$$

Hence the array has the form

Now $K+N+a(N)$ numbers have been entered. Since they must be the numbers $1,2, \cdots, a^{2}(N)+2$, we get

$$
\begin{equation*}
K+N+a(N)=a^{2}(N)+2 \tag{3.7}
\end{equation*}
$$

But

$$
K+a(K)+b(K)=c(K)=a^{2}(N)+1
$$

Therefore

$$
\begin{equation*}
a(K)+b(K)+1=N+a(N) \tag{3.8}
\end{equation*}
$$

Now if we had $a(K)<N$, we would have $a^{2}(K)<a(N)$, but from (3.8) we would have $b(K)+1>a(N)$. However $b(K)=a^{2}(K)+1$ since (3.4) holds for $K<N$. This is a contradiction, since $a(N)<b(K)$. In a similar way we contradict the supposition $a(K)>N$. Hence $a(K)=N$ and we have
$K+N+a(N)=K+a(K)+a^{2}(K)=K+a(K)+b(K)-1=c(K)-1=a^{2}(N)$,
contradicting (3.7).
3. (3.5) and (3.6)). Consider the array:

Assume $\mathrm{ba}(\mathrm{N})>\mathrm{c}(\mathrm{N})$. Then no number $\leq \mathrm{c}(\mathrm{N})$ can be missing from the enclosed portion (since it's too late to enter it in any row). Hence in the enclosed portion we have at least the numbers $1,2, \cdots, c(N), \quad$ ba (N) -1 and $\mathrm{ba}(\mathrm{N})$. However these are only $\mathrm{N}+\mathrm{a}(\mathrm{N})+\mathrm{b}(\mathrm{N})-1=\mathrm{c}(\mathrm{N})-1$ entries, $a$ contradiction. Hence $\mathrm{ba}(\mathrm{N})<\mathrm{c}(\mathrm{N})$ and one number $\mathrm{M}<\mathrm{c}(\mathrm{N})$ is missing from the enclosed portion. Then we must have $M=a b(N)$. Now $M$ is exceeded only by $c(N)$, so we must have $a b(N)=c(N)-1$, ba $(\mathbb{N})=c(N)-2$ proving (3.5) and (3.6).

We conclude this section with a characterization of the array $R$.
Theorem 7. Let $a_{1}, b_{1}$ and $c_{1}$ be strictly monotone functions whose ranges form a disjoint partition of the positive integers. Suppose further that they satisfy (3.3) and (3.4). Then $a_{1}=a, b_{1}=b$ and $c_{1}=c$.

Proof. Clearly

$$
b(N)=a^{2}(N)+1>a^{2}(N) \geq a(N)
$$

Hence we must have $a(1)=1$ and $b(1)=a^{2}(1)+1=2$. Then $c(1)=4$, and further, since $b(N)>a(N), a(2)=3$.

Now by induction on the columns of the array formed by the functions $a_{1}, b_{1}$ and $c_{1}$, we see that it is the array $R$.

## 4. RELATIONS INVOLVING $\mathfrak{f}$

Since every number appears in the range of $f$ and $f$ is monotone, the following definition makes sense. For every $N$, we let $A(N)$ be defined as follows:

$$
\begin{equation*}
\mathrm{f}(\mathrm{~A}(\mathrm{~N}))=\mathrm{N} ; \quad \mathrm{f}(\mathrm{~A}(\mathrm{~N})-1)=\mathrm{N}-1 \tag{4.1}
\end{equation*}
$$

We define $B(N)$ by

$$
\begin{equation*}
\mathrm{B}(\mathrm{~N})=\mathrm{A}(\mathrm{~A}(\mathrm{~N}))+1 \tag{4.2}
\end{equation*}
$$

and $\mathrm{C}(\mathrm{N})$ by

$$
\begin{equation*}
\mathrm{C}(\mathrm{~N})=\mathrm{N}+\mathrm{A}(\mathrm{~N})+\mathrm{B}(\mathrm{~N}) . \tag{4.3}
\end{equation*}
$$

Theorem 8. $\mathrm{A}\left(\mathrm{A}(\mathbb{N}) \subseteq \mathrm{C}_{2}\right.$.
Proof. Suppose for some $N$, $A\left(A(N)\right.$ ) is not in $C_{2}$. Put (canonical representation)

$$
A(A(N))=G_{k}+\epsilon_{k+1} G_{k+1}+\cdots \quad(k>2)
$$

Then applying f we get

$$
\begin{align*}
& A(N)=G_{k-1}+\epsilon_{k+1} G_{k}+\cdots  \tag{4.4}\\
& N=G_{k-2}+\epsilon_{k+1} G_{k-1}+\cdots .
\end{align*}
$$

By the definition of $A$ and Theorem 3, $A(A(N))-1 \notin C_{2}$, so by Theorem 4 , $\mathrm{k} \equiv 2(\bmod 3)$. But neither is $\mathrm{A}(\mathrm{N})-1$ in $\mathrm{C}_{2}$. Hence $\mathrm{k}-1 \equiv 2(\bmod$ 3). This is a contradiction and proves the theorem.

Theorem 9. $\quad C_{2}=A(A(\mathbb{N})) \cup A(B(\mathbb{N}))$.
Proof. Suppose $A(B(N)) \nsubseteq C_{2}$. Put (canonical representation)

$$
A(B(N))=G_{k}+\epsilon_{k+1} G_{k+1}+\cdots \quad(k=2)
$$

As in the previous theorem, we must have $k \equiv 2(\bmod 3)$ so that $k \geq 5$ and

$$
\mathrm{A}(\mathrm{~A}(\mathrm{~N}))+1=\mathrm{B}(\mathrm{~N})=\mathrm{G}_{\mathrm{k}-1}+\epsilon_{\mathrm{k}+1} \mathrm{G}_{\mathrm{k}}+\cdots
$$

Hence

$$
A(A(N))=G_{k-1}-1+\epsilon_{k+1} G_{k}+\cdots
$$

and, from Theorem 5,

$$
A(N)=G_{k-2}+\epsilon_{k+1} G_{k-1}+\cdots
$$

Now again since $A(N)-1 \notin C_{2}$, we get $k-2 \equiv 2(\bmod 3)$, a contradiction.
Theorem 10. Let $K$ be arbitrary and suppose $K-1$ is given canonically by

$$
\begin{equation*}
K-1=\epsilon_{2} G_{2}+\epsilon_{3} G_{3}+\cdots \tag{4.5}
\end{equation*}
$$

Then

$$
\begin{equation*}
A(K)=G_{1}+\epsilon_{2} G_{3}+\epsilon_{3} G_{4}+\cdots \tag{4.6}
\end{equation*}
$$

$$
\begin{equation*}
C(K)=G_{4}+\epsilon_{2} G_{5}+\epsilon_{3} G_{6}+\cdots \tag{4.8}
\end{equation*}
$$

Proof. From the previous theorem, the number

$$
P=G_{2}+\epsilon_{2} G_{4}+\epsilon_{3} G_{5}+\ldots
$$

is either of the form $A(A(L))$ or $A(B(L))$. Hence

$$
f(P)=G_{1}+\epsilon_{2} G_{3}+\epsilon_{3} G_{4}
$$

is either of the form $A(L)$ or $B(L)$. But $f(P)-1 母 C_{2}$, so $f(P)$ cannot have the form $B(L)$. Hence $P$ is, in fact, $A(A(K))$ and all of the relations follow, the third using (4.2) and (4.3).

Theorem 11. $\mathrm{A}=\mathrm{a}, \mathrm{B}=\mathrm{b}, \mathrm{C}=\mathrm{c}$ and for any integer N ,

$$
\left\{\begin{array}{l}
\mathrm{f}(\mathrm{a}(\mathrm{~N}))=\mathrm{N}  \tag{4.9}\\
\mathrm{f}(\mathrm{~b}(\mathrm{~N}))=\mathrm{a}(\mathrm{~N}) \\
\mathrm{f}(\mathrm{c}(\mathrm{~N}))=\mathrm{b}(\mathrm{~N})
\end{array}\right.
$$

Proof. We prove the first part of the theorem by verifying the conditions of Theorem 7. The second part will be established incidentally in the

$$
\mathrm{f}(\mathrm{~B}(\mathrm{~N})-1)=\mathrm{f}(\mathrm{~A}(\mathrm{~A}(\mathrm{~N})))=\mathrm{f}(\mathrm{~B}(\mathrm{~N}))
$$

Hence $B(N) \notin A(\mathbb{N})$ (and $f(B(\mathbb{N}))=A(N)$ ). Now

$$
\mathrm{C}(\mathrm{~N})=\mathrm{N}+\mathrm{A}(\mathrm{~N})+\mathrm{A}(\mathrm{~A}(\mathrm{~N}))+1 .
$$

Let (canonical representation)

$$
A(A(N))=G_{2}+\epsilon_{3} G_{3}+\epsilon_{4} G_{4}+\cdots
$$

Then

$$
A(N)-1=\epsilon_{3} G_{2}+\epsilon_{4} G_{4}+\cdots,
$$

and, since $A(N)-1 \notin C_{2}$, it follows that $\epsilon_{3}=0$. Applying $f$ we get

$$
N-1=\epsilon_{3} G_{1}+\epsilon_{4} G_{2}+\cdots
$$

so that

$$
\begin{aligned}
\mathrm{C}(\mathrm{~N}) & =3+\mathrm{F}_{2}+\epsilon_{3} \mathrm{G}_{4}+\epsilon_{4} \mathrm{G}_{5}+\cdots \\
& =\mathrm{G}_{4}+\epsilon_{4} \mathrm{G}_{5}+\epsilon_{5} \mathrm{G}_{6}+\cdots
\end{aligned}
$$

This is not necessarily the canonical representation of $\mathrm{C}(\mathrm{N})$ but

$$
\mathrm{f}(\mathrm{C}(\mathrm{~N}))=\mathrm{A}(\mathrm{~A}(\mathrm{~N}))+1 \quad(=\mathrm{B}(\mathrm{~N}))
$$

and

$$
\mathrm{f}(\mathrm{C}(\mathrm{~N})-1)=\mathrm{A}(\mathrm{~A}(\mathrm{~N}))+1
$$

Hence $C(N) \notin A(\mathbb{N})$. Now suppose $C(N)=A(A(\mathbb{N}))+1$ for some $M$. Then

$$
\mathrm{B}(\mathrm{~N})=\mathrm{A}(\mathrm{~A}(\mathrm{~N}))+1=\mathrm{f}(\mathrm{C}(\mathrm{n}))=\mathrm{A}(\mathbb{M})
$$

a contradiction. Hence we have shown that $A(\mathbb{N}), B(\mathbb{N})$ and $C(\mathbb{N})$ are disjoint.

Now suppose $N \notin A(\mathbb{N}) \cup B(\mathbb{N})$. Let (canonical representation)

$$
\begin{equation*}
N=G_{k}+\epsilon_{k+1} G_{k+1}+\cdots \tag{4.10}
\end{equation*}
$$

By Theorem 9 this is equivalent to assuming $A(N) \notin C_{2}$, that is,

$$
\begin{equation*}
A(N)=G_{k+1}+\epsilon_{k+1} G_{k+2}+\cdots \tag{4.11}
\end{equation*}
$$

and since, always, $A(N)-1 \notin C_{2}$, we have $k+1 \equiv 2(\bmod 3)$, that is, $\mathrm{k} \equiv 1(\bmod 3)$ 。

First let us consider the case $k=4$. Then, if we put

$$
\begin{equation*}
K-1=\epsilon_{5} \mathrm{G}_{2}+\epsilon_{6} \mathrm{G}_{3}+\cdots \tag{4.12}
\end{equation*}
$$

we get, by Theorem 10,

$$
\mathrm{c}(\mathrm{~K})=\mathrm{N}
$$

Now suppose $\mathrm{k}>4 ; \mathrm{k}=3 \mathrm{t}+1$, $\mathrm{t}>1$. Then let $\mathrm{s}=\mathrm{t}-1$ and set

$$
\begin{aligned}
K & =G_{3 s+1}+\epsilon_{3 t+2} G_{3 s+2}+\cdots \\
& =G_{-2}+\left(G_{-1}+G_{0}\right)+\left(G_{2}+G_{3}\right)+\cdots+\left(G_{3 s-1}+G_{3 s}\right)+\epsilon_{3 t-2} G_{3 s+2}
\end{aligned}
$$

Now, applying Theorem 10 to $\mathrm{K}-\left(\mathrm{G}_{-2}+\left(\mathrm{G}_{-1}+\mathrm{G}_{0}\right)\right)$, we get

$$
\begin{aligned}
C(K & \left.-\left(G_{-2}+G_{-1}+G_{0}\right)+1\right) \\
& =G_{4}+\left(G_{5}+G_{6}\right)+\cdots+\left(G_{3 t-1}+G_{3 t}\right)+\epsilon_{3 t+2} G_{3 t+2}+\cdots \\
& =N_{0}
\end{aligned}
$$

This proves the Theorem.

## 5. THE SECOND CANONICAL REPRESENTATION

Theorem 12. Every positive integer N can be written in a unique way in the form

$$
\begin{equation*}
N=G_{3 s+1}+\epsilon_{3 s+2} G_{3 s+2}+\cdots \tag{5.1}
\end{equation*}
$$

where $s=0$ and, as before, $\boldsymbol{\epsilon}_{\mathbf{i}} \boldsymbol{\epsilon}_{\mathrm{i}+1} \boldsymbol{\epsilon}_{\mathrm{i}+2}=0$. Moreover,

$$
\begin{equation*}
a(N)=G_{3 s+2}+\epsilon_{3 s+2} G_{3 s+3}+\cdots, \tag{5.2}
\end{equation*}
$$

$$
\begin{equation*}
b(N)=G_{3 s+3}+\epsilon_{3 s+2} G_{3 s+4}+\cdots \tag{5.3}
\end{equation*}
$$

and

$$
\begin{equation*}
c(N)=G_{3 s+4}+\epsilon_{3 s+2} G_{3 s+5}+\cdots \tag{5.4}
\end{equation*}
$$

Proof. We saw in the proof of the previous theorem that an integer M is of the form $\mathrm{c}(\mathrm{K})$ if and only if it is given canonically by

$$
M=G_{k}+\epsilon_{k+1} G_{k+1}+\cdots, \quad k \equiv 1(\bmod 3)
$$

Hence for some $s \geq 0, c(N)$ is given canonically by

$$
\mathrm{c}(\mathrm{~N})=\mathrm{G}_{3 \mathrm{~s}+4}+\epsilon_{3 \mathrm{~s}+2} \mathrm{G}_{3 \mathrm{~s}+5}+\cdots
$$

Apply f repeatedly to get the existence of the representation and formulas (5.2) and (5.3). Now if we assume that $N$ can be written in two different ways in the form (5.1), we should obtain two different canonical representations of $c(N)$. Hence the theorem is proved.

We may call (5.1) the second canonical representation.
In view of the representation (5.1), it is natural to let $C_{3 s+1}$ denote the set of integers representable in the form (5.1), for a fixed $s$. Then
clearly

$$
\begin{equation*}
\overline{\mathrm{C}}_{3 \mathrm{~s}+1}=\mathrm{C}_{3 \mathrm{~s}+1} \quad(\mathrm{~s} \geq 1) \tag{5.5}
\end{equation*}
$$

while

$$
\begin{equation*}
\overline{\mathrm{C}}_{1}=\bigcup_{\mathrm{k}=0}^{\infty}\left(\mathrm{C}_{3 \mathrm{k}+2} \bigcup \mathrm{C}_{3 \mathrm{k}+3}\right) \tag{5.6}
\end{equation*}
$$

Making use of the last theorem, we obtain several formulas relating $a, b$ and $c$. The details are similar in all cases so we will prove only two of the formulas.

Theorem 13. The following formulas hold.

$$
\left\{\begin{array}{l}
\mathrm{a}^{2}=\mathrm{b}-1  \tag{5.7}\\
\mathrm{ab}=\mathrm{c}-1 \\
\mathrm{ac}=\mathrm{a}+\mathrm{b}+\mathrm{c} \\
\mathrm{ba}=\mathrm{c}-2 \\
\mathrm{~b}^{2}=\mathrm{a}+\mathrm{b}+\mathrm{c}-1 \\
\mathrm{bc}=\mathrm{a}+2 \mathrm{~b}+2 \mathrm{c} \\
\mathrm{ca}=\mathrm{a}+\mathrm{b}+\mathrm{c}-3 \\
\mathrm{cb}=\mathrm{a}+2 \mathrm{~b}+2 \mathrm{c}-2 \\
\mathrm{c}^{2}=2 \mathrm{a}+3 \mathrm{~b}+4 \mathrm{c}
\end{array}\right.
$$

Proof. To prove, for instance, that

$$
b c=a+2 b+2 c
$$

we suppose that

$$
\begin{equation*}
\mathrm{c}(\mathrm{~N})=\mathrm{G}_{3 \mathrm{~s}+1}+\epsilon_{3 \mathrm{~s}+2} \mathrm{G}_{3 \mathrm{~s}+2}+\cdots \quad(\mathrm{s} \geq 1) \tag{5.8}
\end{equation*}
$$

Then by Theorem 12

$$
\mathrm{bc}(\mathrm{~N})=\mathrm{G}_{3 \mathrm{~s}+3}+\epsilon_{3 \mathrm{~s}+2} \mathrm{G}_{3 \mathrm{~s}+4}+\ldots \quad(\mathrm{s} \geq 1)
$$

But, by applying $f$ to $c(N)$ we see that

$$
\mathrm{b}(\mathrm{~N})=\mathrm{G}_{3 \mathrm{~s}}+\epsilon_{3 \mathrm{~s}+2} \mathrm{G}_{3 \mathrm{~s}+1}+\cdots \quad(\mathrm{s} \geq 1)
$$

and

$$
a(N)=G_{3 s-1}+\epsilon_{3 s+2} G_{3 s}+\cdots \quad(s \geq 1)
$$

Now the result follows if we observe that

$$
G_{n-1}+2 G_{n}+2 G_{n-1}=G_{n+3}
$$

Similarly, to prove that

$$
b^{2}=a+b+c-1
$$

suppose that

$$
\mathrm{c}(\mathrm{~N})=\mathrm{G}_{3 \mathrm{~s}+1}+\epsilon_{3 \mathrm{~s}+2} \mathrm{G}_{3 \mathrm{~s}+2}+\cdots \quad(\mathrm{s} \geq 1)
$$

Then

$$
b(N)=G_{3 s}+\epsilon_{3 s+2} G_{3 s+1}+\cdots \quad(s \geq 1)
$$

and

$$
a(N)=G_{2 s-1}+\epsilon_{3 s+2} G_{3 s}+\cdots \quad(s \geq 1)
$$

Now we write $b(N)$ in the second canonical form:

$$
\mathrm{b}(\mathrm{~N})=\left(\mathrm{G}_{1}+\mathrm{G}_{2}\right)+\cdots+\left(\mathrm{G}_{3 \mathrm{~s}-2}+\mathrm{G}_{3 \mathrm{~s}-1}\right)+\epsilon_{3 \mathrm{~s}+2} \mathrm{G}_{3 \mathrm{~s}+1}+\cdots .
$$

Then

$$
\mathrm{b}^{2}(\mathrm{n})=\left(\mathrm{G}_{3}+\mathrm{G}_{4}\right)+\cdots+\left(\mathrm{G}_{3 \mathrm{~s}}+\mathrm{G}_{3 \mathrm{~s}+1}\right)+\epsilon_{3 \mathrm{~s}+2} \mathrm{G}_{3 \mathrm{~s}+3}+\cdots
$$

Hence

$$
b^{2}(\mathrm{~N})+1=\mathrm{b}^{2}(\mathrm{~N})+\mathrm{G}_{2}=\mathrm{a}(\mathrm{~N})+\mathrm{b}(\mathrm{~N})+\mathrm{c}(\mathrm{~N}) .
$$

A word function (or simply word) $u$ is a monomial in $a, b, c$ :

$$
\begin{equation*}
u=a^{i_{1}} b^{j_{1}} c^{k_{1}} \ldots a^{i_{r}} b^{j_{r}} c^{k_{r}} \tag{5.9}
\end{equation*}
$$

where the exponents are arbitrary nonnegative integers. Since $a u=b v$, for example, is impossible, and $a u=a v$ implies $u=v$, it follows that the representation (5.9) is unique. In other words factorization into prime elements $a, b, c$ is unique. We define the weight of a word by means of

$$
\mathrm{p}(\mathrm{a})=1, \quad \mathrm{p}(\mathrm{~b})=2, \quad \mathrm{p}(\mathrm{c})=3
$$

together with

$$
\mathrm{p}(\mathrm{uv})=\mathrm{p}(\mathrm{u})+\mathrm{p}(\mathrm{v})
$$

where $u, v$ are arbitrary words. Let $N_{p}$ denote the number of words of weight $p$. If $u$ is any such word then either

$$
u=a u_{1}, \quad u=b u_{2} \quad \text { or } \quad u=c u_{3}
$$

where

$$
\mathrm{p}\left(\mathrm{u}_{1}\right)=\mathrm{p}-1, \quad \mathrm{p}\left(\mathrm{u}_{2}\right)=\mathrm{p}-2, \quad \mathrm{p}\left(\mathrm{u}_{3}\right)=\mathrm{p}-3 .
$$

Hence

$$
N_{p}=N_{p-1}+N_{p-2}+N_{p-3} \quad(p \geq 3)
$$

Moreover

$$
N_{0}=N_{1}=1, \quad N_{2}=2
$$

It follows that

$$
\begin{equation*}
N_{p}=G_{p+1} \tag{5.10}
\end{equation*}
$$

Theorem 14. The words $u, v$ satisfy

$$
\begin{equation*}
u v=v u \tag{5.11}
\end{equation*}
$$

if and only if there is a word $w$ such that

$$
u=w^{r}, \quad v=w^{s}
$$

where r and s are nonnegative integers.
Proof. The proof is by induction on $p(u)+p(v)$. We may assume that both $u, v$ have positive weight. Also we may assume that $p(u) \geq p(v)$. It then follows from (5.11) and unique factorization that $u=v z$, where $z$ is a word. Thus (5.11) reduces to

$$
\begin{equation*}
\mathrm{zv}=\mathrm{vz} \tag{5.12}
\end{equation*}
$$

Since $p(z v)<p(u v)$, the inductive hypothesis gives

$$
\mathrm{z}=\mathrm{w}^{\mathrm{r}}, \quad \mathrm{v}=\mathrm{w}^{\mathrm{s}}
$$

so that $u=w^{r+s}$.
For the next theorem we require, in addition to the weight of $u$, the degree of $u, d(u)$, defined by

$$
\begin{equation*}
\mathrm{d}(\mathrm{u})=\mathrm{i}_{1}+\mathrm{j}_{1}+\mathrm{k}_{1}+\cdots+\mathrm{i}_{\mathrm{r}}+\mathrm{j}_{\mathrm{r}}+\mathrm{k}_{\mathrm{r}} \tag{5.13}
\end{equation*}
$$

where $u$ is given by (5.9). We also define the integers $H_{n}$ by means of

$$
\begin{equation*}
\mathrm{H}_{0}=0, \quad \mathrm{H}_{1}=1, \quad \mathrm{H}_{2}=2, \quad \mathrm{H}_{\mathrm{n}+1}=\mathrm{H}_{\mathrm{n}}+\mathrm{H}_{\mathrm{n}-1}+\mathrm{H}_{\mathrm{n}-2} \quad(\mathrm{n} \geq 2) \tag{5.14}
\end{equation*}
$$

It is easy to show that

$$
\begin{equation*}
H_{n}=G_{n}+G_{n-1} \tag{5.15}
\end{equation*}
$$

Theorem 15. Let $u$ be a word of weight $p$. Then

$$
\begin{equation*}
\mathrm{u}(\mathrm{n})=\mathrm{G}_{\mathrm{p}-3} \mathrm{a}(\mathrm{n})+\mathrm{H}_{\mathrm{p}-3} \mathrm{~b}(\mathrm{n})+\mathrm{G}_{\mathrm{p}-2} \mathrm{c}(\mathrm{n})=\lambda_{\mathrm{u}}, \tag{5.16}
\end{equation*}
$$

where $\lambda_{u}$ is independent of $n$ but depends on $u$.
To have the theorem hold for all $p \geq 1$ we extend the definition of $\mathrm{G}_{\mathrm{n}}, \mathrm{H}_{\mathrm{n}}$ for negative values of n . In particular, we have the following table of values

| n | -3 | -2 | -1 | 0 | 1 | 2 | 3 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| G | -1 | 1 | 0 | 0 | 1 | 1 | 2 |
| H | -1 | 0 | 1 | 0 | 1 | 2 | 3 |

It is now easily verified that the theorem holds for the words $a, b$ and c. We assume that (5.16) holds for words of degree $k$. Let $u$ be an arbitrary word of degree $k+1$. There are three cases according as $u=v a$, vb or vc. Assume $v$ has weight $p$.
(i) For $u=v a$, we have, by the inductive hypothesis and Theorem 13,

$$
\begin{aligned}
u= & v a=G_{p-3} a^{2}+H_{p-3} b a+g_{p-2} c a-\lambda_{v} \\
= & G_{p-3}(b-1)+H_{p-3}(c-2)+G_{p-2}(a+b+c-3)-\lambda_{v} \\
= & G_{p-2} a+\left(G_{p-2}+G_{p-3}\right) b+\left(H_{p-3}+G_{p-2}\right) c-\left(G_{p-3}+2 H_{p-3}+3 G_{p-2}+\lambda_{v}\right) \\
= & G_{p-2} a+H_{p-2} b+G_{p-1} c-\left(H_{p}+\lambda_{v}\right) . \\
& \text { (ii) For } u=v b, \text { we have }
\end{aligned}
$$

$$
\begin{aligned}
u= & v b=G_{p-3} a b+H_{p-3} b^{2}+G_{p-2} c b-\lambda_{v} \\
= & G_{p-3}(c-1)+H_{p-3}(a+b+c-1)+G_{p-2}(a+2 b+2 c-2)-\lambda_{v} \\
= & \left(G_{p-2}+H_{p-3}\right) a+\left(2 G_{p-2}+H_{p-3}\right) b+\left(2 G_{p-2}+G_{p-3}+H_{p-3}\right) c \\
= & \quad-\left(2 G_{p-2}+G_{p-3}+H_{p-3}+\lambda_{v}\right) \\
= & G_{p-1} a+H_{p-1} b+G_{p} c-\left(G_{p}+\lambda_{v}\right) . \\
& (\text { (ii) For } u=v c, \text { we have } \\
u= & v c=G_{p-3} a c+H_{p-3} b c+G_{p-2} c^{2}-\lambda_{v} \\
= & G_{p-3}(a+b+c)+H_{p-3}(a+2 b+2 c)+G_{p-2}(2 a+3 b+4 c)=\lambda_{v} \\
= & \left(2 G_{p-2}+G_{p-3}+H_{p-3}\right) a+\left(3 G_{p-2}+G_{p-3}+2 H_{p-3}\right) b \\
= & +\left(4 G_{p-2}+G_{p-3}+2 H_{p-3}\right) c=\lambda_{v} \\
&
\end{aligned}
$$

This completes the proof. Incidentally, we have proved the following relations:

$$
\left\{\begin{array}{l}
\lambda_{\mathrm{va}}=H_{\mathrm{p}}+\lambda_{\mathrm{v}}  \tag{5.17}\\
\lambda_{\mathrm{vb}}=G_{\mathrm{p}}+\lambda_{\mathrm{v}} \\
\lambda_{\mathrm{vc}}=\lambda_{\mathrm{v}}
\end{array}\right.
$$

where v is of weight p .
As an immediate corollary of the last theorem, we state:
Theorem 16. Let $u$ and $v$ be arbitrary words. Then there is an integer $C$ such that

$$
\begin{equation*}
u v-v u=C . \tag{5.18}
\end{equation*}
$$

## 6. AN ESTIMATE OF $a(n)$

Let $\alpha$ be the real root of $x^{3}-x^{2}-x-1=0$ and let $\beta$ and $\gamma$ be the complex roots, $\beta=r e^{i \theta}, \gamma=r e^{-\mathrm{i} \theta}$. Then we have

$$
\mathrm{G}_{\mathrm{n}+1}-\alpha \mathrm{G}_{\mathrm{n}}=\frac{\gamma^{\mathrm{n}+1}-\beta^{\mathrm{n}+1}}{\gamma-\beta}
$$

which we can verify by taking n equal to $-1,0$ and 1 and noting that both sides of (6.1) satisfy the recurrence

$$
u_{n+3}=u_{n+2}+u_{n+1}+u_{n} .
$$

If N is given in the second canonical represent ation by

$$
\begin{equation*}
\mathrm{N}=\mathrm{G}_{3 \mathrm{k}+1}+\epsilon_{3 \mathrm{k}+2} \mathrm{G}_{3 \mathrm{k}+2}+\cdots \quad(\mathrm{k} \geq 0) \tag{6.2}
\end{equation*}
$$

we have

$$
\left\{\begin{array}{l}
\mathrm{a}(\mathrm{~N})=\mathrm{G}_{3 \mathrm{k}+2}+\epsilon_{3 \mathrm{k}+2} \mathrm{G}_{3 \mathrm{k}+3}+\cdots  \tag{6.3}\\
\mathrm{b}(\mathrm{~N})=\mathrm{G}_{3 \mathrm{k}+3}+\epsilon_{3 \mathrm{k}+2} \mathrm{G}_{3 \mathrm{k}+4}+\cdots \\
\mathrm{c}(\mathrm{~N})=\mathrm{G}_{3 \mathrm{k}+4}+\epsilon_{3 \mathrm{k}+2} \mathrm{G}_{3 \mathrm{k}+5}+\cdots .
\end{array}\right.
$$

Now $\alpha=1.8, \cdots$, so that $|\beta|=|\gamma|=\sqrt{\beta \gamma}=\sqrt{1 / \alpha}<1$. Then, using (6.1), (6.2), and (6.3) we get the following.

Theorem 17. The three sequences

$$
\mathrm{a}(\mathrm{~N})-[\alpha \mathrm{N}], \quad \mathrm{b}(\mathrm{~N})-\left[\alpha^{2} \mathrm{~N}\right], \quad \mathrm{c}(\mathbb{N})-\left[\alpha^{3} \mathrm{~N}\right]
$$

are all bounded.
Next we prove
Theorem 18. The difference $\mathrm{a}(\mathrm{N})-[\alpha \mathrm{N}]$ is positive infinitely often, negative infinitely often and 0 infinitely often.

Proof. If $\theta$ were a rational multiple of $2 \pi$ we should have, for some m,

$$
\gamma^{\mathrm{m}+1}=\beta^{\mathrm{m}+1}=\mathrm{r}^{\mathrm{m}+1}
$$

and, by (6.1), $G_{m+1}=\alpha G_{m}$. But $\alpha$ is irrational so this is impossible. Hence for infinitely many $k$ we must have

$$
\begin{equation*}
\mathrm{G}_{3 \mathrm{k}+2}-\alpha \mathrm{G}_{3 \mathrm{k}+1}=\mathrm{r}^{3 \mathrm{k}+1} \frac{\sin \{(3 \mathrm{k}+2) \theta\}}{\sin \theta}>0 \tag{6.4}
\end{equation*}
$$

that is,

$$
\mathrm{a}\left(\mathrm{G}_{3 \mathrm{k}+1}\right)-\left[\alpha \mathrm{G}_{3 \mathrm{k}+1}\right]>0
$$

for infinitely many k .
To get the second part of the theorem we must find an infinite number of integers N for which

$$
\mathrm{a}(\mathrm{~N})-\alpha \mathrm{N}<-1
$$

Let N have the form

$$
\mathrm{N}=\mathrm{G}_{1}+\mathrm{G}_{3}+\mathrm{G}_{\mathrm{k}}
$$

where $k$ is very large. Then

$$
\begin{aligned}
\mathrm{a}(\mathrm{~N})-\alpha \mathrm{N} & =\mathrm{G}_{2}-\alpha \mathrm{G}_{1}+\mathrm{G}_{4}-\alpha \mathrm{G}_{3}+\mathrm{G}_{\mathrm{k}+1}-\beta \mathrm{G}_{\mathrm{k}} \\
& =1-\alpha+3-2 \alpha+\mathrm{G}_{\mathrm{k}+1}-\alpha \mathrm{G}_{\mathrm{k}} \approx-1.4
\end{aligned}
$$

This proves the theorem.
Finally to prove that the difference vanishes infinitely often, it suffices to show that (compare (6.4))

$$
-1 \leq \mathrm{r}^{3 \mathrm{k}+1} \frac{\sin (3 \mathrm{k}+2)}{\sin \theta}<0
$$

for infinitely many values of $n$. This is clear since $0<r<1$ and $\theta$ is an irrational multiple of $2 \pi$.

## 7. GENERATING FUNCTIONS

Put

$$
\begin{equation*}
\phi_{\mathrm{k}}(\mathrm{x})=\sum_{\mathrm{n} \in \mathrm{C}_{\mathrm{k}}} \mathrm{x}^{\mathrm{n}} \quad(\mathrm{k}=2,3,4, \cdots) \tag{7.1}
\end{equation*}
$$

and

$$
\begin{equation*}
\Phi_{3 k+1}(x)=\sum_{n \in \overline{\mathrm{C}}_{3 k+1}} x^{n} \quad(k=0,1,2, \cdots) \tag{7.2}
\end{equation*}
$$

In view of (5.5) and (5.6), we have

$$
\begin{equation*}
\phi_{3 \mathrm{k}+1}(\mathrm{x})=\phi_{3 \mathrm{k}+1}(\mathrm{x}) \quad(\mathrm{k}=1,2,3, \cdots) \tag{7.3}
\end{equation*}
$$

and

$$
\begin{equation*}
\bar{\phi}_{1}(x)=\sum_{k=0}^{\infty} \phi_{3 k+2}(x)+\sum_{k=0}^{\infty} \phi_{3 k+3}(x) \tag{7.4}
\end{equation*}
$$

It is evident that
(7.5)

$$
\frac{x}{1-x}=\sum_{k=2}^{\infty} \phi_{k}(x)
$$

Also it follows from the definition of $\mathrm{C}_{\mathrm{k}}$ that
(7.6)

$$
\begin{aligned}
\phi_{k}(x)= & x^{G_{k}}\left\{1+\sum_{j=k+2}^{\infty} \phi_{j}(x)\right\} \\
& +x^{G_{k}+G_{k+1}}\left\{1+\sum_{j=k+3}^{\infty} \phi_{j}(x)\right\} .
\end{aligned}
$$

From (1.1) we get the recurrence

$$
\begin{align*}
& \left(1+x^{G}{ }^{k+1}\right)\left(\phi_{k+1}(x)+x^{G}{ }^{G+1}+G_{k+2} \phi_{k+3}(x)\right)  \tag{7.7}\\
& \quad=x^{G_{k+1}-G_{k}}\left(1+x^{G+2}\right)\left(\phi_{k}(x)-x^{G}{ }^{G_{k}} \phi_{k+2}(x)\right)
\end{align*}
$$

It is also convenient to define
(7.8) $\quad A(x)=\sum_{n=1}^{\infty} x^{a(n)}, \quad B(x)=\sum_{n=1}^{\infty} x^{b(n)}, \quad C(x)=\sum_{n=1}^{\infty} x^{c(n)}$,
so that

$$
\begin{equation*}
A(x)+B(x)+C(x)=\frac{x}{1-x} \tag{7.9}
\end{equation*}
$$

Moreover

$$
\begin{gather*}
A(x)=\sum_{k=0}^{\infty} \phi_{3 k+2}(x)  \tag{7.10}\\
B(x)=\sum_{k=0}^{\infty} \phi_{3 k+3}(x)  \tag{7.11}\\
C(x)=\sum_{k=0}^{\infty} \phi_{3 k+4}(x)=\frac{x}{1-x}-\Phi_{1}(x) \tag{7.12}
\end{gather*}
$$

Now by (7.1) and (1.12)

$$
\phi_{2}(x)=\sum_{n=1}^{\infty} x^{a^{2}(n)}+\sum_{n=1}^{\infty} x^{a b(n)}
$$

Since

$$
a^{2}(\mathrm{~N})=\mathrm{b}(\mathrm{n})-1, \quad \mathrm{ab}(\mathrm{n})=\mathrm{c}(\mathrm{n})-1,
$$

It follows that
(7.13)

$$
\mathrm{x} \phi_{2}(\mathrm{x})=\mathrm{B}(\mathrm{x})+\mathrm{C}(\mathrm{x}) .
$$

In the next place, by (1.13)

$$
\begin{aligned}
\phi_{3}(x) & =\sum_{n=1}^{\infty} x^{b a(n)}+\sum_{n=1}^{\infty} x^{b^{2}(n)} \\
& =x^{-2} C(x)+x^{-1} \sum_{n=1}^{\infty} x^{a(n)+b(n)+c(n)} .
\end{aligned}
$$

Since

$$
\begin{aligned}
A(x) & =\sum_{n=1}^{\infty} x^{a^{2}(n)}+\sum_{n=1}^{\infty} x^{a b(n)}+\sum_{n=1}^{\infty} x^{a c(n)} \\
& =x^{-1} A(x)+x^{-1} B(x)+\sum_{n=1}^{\infty} x^{a(n)+b(n)+c(n)}
\end{aligned}
$$

it follows that

$$
\begin{equation*}
\mathrm{x}^{2} \phi_{3}(\mathrm{x})=\mathrm{xA}(\mathrm{x})-\mathrm{B}(\mathrm{x}) . \tag{7.14}
\end{equation*}
$$

By (1.1)

$$
\begin{aligned}
\phi_{2}(x) & =x\left\{1+\sum_{j=4}^{\infty} \phi_{j}(x)\right\}+x^{3}\left\{1+\sum_{j=5}^{\infty} \phi_{j}(x)\right\} \\
& =x+x^{3}+x \phi_{4}(x)+\left(x+x^{3}\right) \sum_{j=5}^{\infty} \phi_{j}(x) \\
& =x+x^{3}+x \phi_{4}(x)+\left(x+x^{3}\right)\left\{\frac{x}{1-x}-\phi_{2}(x)-\phi_{3}(x)-\phi_{4}(x)\right\}
\end{aligned}
$$

Combining this with (7.13) and (7.14), we get

$$
\begin{equation*}
x^{4} \phi_{4}(x)=x^{2} n(x)-C(x) \tag{7.15}
\end{equation*}
$$

In a similar manner we get

$$
\begin{equation*}
\mathrm{x}^{8} \phi_{5}(\mathrm{x})=-\mathrm{xA}(\mathrm{x})+\mathrm{B}(\mathrm{x})+\left(1+\mathrm{x}^{4}\right) \mathrm{C}(\mathrm{x}) \tag{7.16}
\end{equation*}
$$

$$
\begin{equation*}
\mathrm{x}^{15} \phi_{6}(\mathrm{x})=\left(\mathrm{x}+\mathrm{x}^{8}\right) \mathrm{A}(\mathrm{x})-\left(1+\mathrm{x}^{2}+\mathrm{x}^{7}\right) \mathrm{B}(\mathrm{x})-\mathrm{x}^{7} \mathrm{C}(\mathrm{x}) . \tag{7.17}
\end{equation*}
$$

Generally it can be shown that

$$
\begin{equation*}
\mathrm{x}^{\mathrm{S}-1} \phi_{\mathrm{k}}(\mathrm{x})=\mathrm{p}_{1}(\mathrm{x}) \mathrm{A}(\mathrm{x})+\mathrm{p}_{2}(\mathrm{x}) \mathrm{B}(\mathrm{x})+\mathrm{p}_{3}(\mathrm{x}) \mathrm{C}(\mathrm{x}) \tag{7.18}
\end{equation*}
$$

where

$$
\mathrm{S}_{\mathrm{k}}=\mathrm{G}_{1}+\mathrm{G}_{2}+\cdots+\mathrm{G}_{\mathrm{k}}
$$

and $p_{1}(x), p_{2}(x), p_{3}(x)$ are polynomials with integral coefficients.
In the next place, exactly as in $[1$, Sec. 7$]$, we can show that $A(x)$, $B(x)$ and $C(x)$ cannot be continued analytically across the unit circle. For the proof it suffices to use

$$
\begin{equation*}
\sum_{a(k) \leq n} 1 \sim \frac{n}{\alpha}, \quad \sum_{b(k) \leq n} 1 \sim \frac{n}{\alpha^{2}}, \quad \sum_{c(k) \leq n} 1 \sim \frac{n}{\alpha^{3}} . \tag{7.19}
\end{equation*}
$$

which follow from Theorem 17. Indeed, we can show in this way that none of the functions can be continued across the unit circle. Moreover if we put

$$
\phi_{\mathrm{k}}(\mathrm{x})=\phi_{\mathrm{k}}^{\mathrm{a}}(\mathrm{x})+\phi_{\mathrm{k}}^{(\mathrm{b})}(\mathrm{x})
$$

where (compare (1.12), (1.13), (1.14))

$$
\begin{aligned}
& \phi_{3 k+2}^{a}(x)=\sum_{n=1}^{\infty} x^{a c^{k} a(n)} ; \quad \phi_{3 k+3}^{a}(x)=\sum_{n=1}^{\infty} x^{b c^{k} a(n)}, \\
& \phi_{3 k+4}(x)=\sum_{n=1}^{\infty} x^{c^{k+1} a(n)}, \quad \phi_{3 k+2}^{b}(x)=\sum_{n=1}^{\infty} x^{a c^{k} b(n)}, \\
& \phi_{3 k+3}^{b}(x)=\sum_{n=1}^{\infty} x^{b c^{k} b(n)}, \quad \phi_{3 k+4}^{b}(x)=\sum_{n=1}^{\infty} x^{c^{k+1} b(n)},
\end{aligned}
$$

then neither $\phi_{\mathrm{k}}^{\mathrm{a}}(\mathrm{x})$ nor $\phi_{\mathrm{k}}^{\mathrm{b}}(\mathrm{x})$ can be continued across the unit circle.
We can also show that $A(x), B(x), C(x)$ do not satisfy any relation of the form

$$
\begin{equation*}
\mathrm{f}_{1}(\mathrm{x}) \mathrm{A}(\mathrm{x})+\mathrm{f}_{2}(\mathrm{x}) \mathrm{B}(\mathrm{x})+\mathrm{f}_{3}(\mathrm{x}) \mathrm{C}(\mathrm{x})=0, \tag{7.20}
\end{equation*}
$$

where $f_{1}(x), f_{2}(x), f_{3}(x)$ are polynomials. In the first place we may assume without loss of generality that the coefficients of $f_{1}(x)$ are rational (for proof compare [3, p. 141, No. 151]) and that

$$
\begin{equation*}
\left(f_{1}(x), \quad f_{2}(x), \quad f_{3}(x)\right)=1 \tag{7.21}
\end{equation*}
$$

Since (7.19) implies
$\lim _{x}(1-x) A(x)=\frac{1}{\alpha} \quad \lim _{x}(1-x) B(x)=\frac{1}{\alpha^{2}}, \quad \lim _{1}(1-x) C(x)=\frac{1}{\alpha^{3}}$,
