## 1. INTRODUCTION AND SUMMARY

Consider the sequence defined by

$$
\begin{equation*}
u_{0}=0, \quad u_{1}=1, \quad u_{n+1}=u_{n}+2 u_{n-1} \quad(n \geq 1) \tag{1.1}
\end{equation*}
$$

It follows at once from (1.1) that

$$
\begin{equation*}
u_{n}=\frac{1}{3}\left(2^{n}-(-1)^{n}\right), \quad u_{n}+u_{n+1}=2^{n} \tag{1.2}
\end{equation*}
$$

The first few values of $u_{n}$ are easily computed.

| n | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $u_{\mathrm{n}}$ | 1 | 1 | 3 | 5 | 11 | 21 | 43 | 85 | 171 | 341 |

It is not difficult to show that the sums

$$
\begin{equation*}
\sum_{i=2}^{k} \epsilon_{i} u_{i} \quad(k=2,3,4, \cdots), \tag{1.3}
\end{equation*}
$$

where each $\epsilon_{i}=0$ or 1 , are distinct. The first few numbers in (1.3) are

$$
1,3,4,5,6,8,9,11,12,14,15,16,17,19,20, \cdots .
$$

Thus there is a sequence of "missing" numbers beginning with

$$
\begin{equation*}
2,7,10,13,18,23,28,31,34,39, \cdots \tag{1.4}
\end{equation*}
$$

In order to identify the sequence (1.4) we first define an array of positive integers $R$ in the following way. The elements of the first row are denoted by $a(n)$, of the second row by $b(n)$, of the third row by $c(n)$. Put

[^0]$$
\mathrm{a}(1)=1, \quad \mathrm{~b}(1)=3, \quad \mathrm{c}(1)=2 .
$$

Assume that the first $n-1$ columns of $R$ have been filled. Then $a(n)$ is the smallest integer not already appearing, while
(1.5)
$b(n)=a(n)+2 n$
and
(1.6)

$$
c(n)=b(n)-1 .
$$

The sets $\{a(n)\},\{b(n)\},\{c(n)\}$ constitute a disjoint partition of the positive integers. The following table is readily constructed.

| n | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| a | 1 | 4 | 5 | 6 | 9 | 12 | 15 | 16 | 17 | 20 | 21 | 22 |
| b | 3 | 8 | 11 | 14 | 19 | 24 | 29 | 32 | 35 | 40 | 43 | 48 |
| c | 2 | 7 | 10 | 13 | 18 | 23 | 28 | 31 | 34 | 39 | 42 | 47 |

The table suggests that the numbers $c(n)$ are the "missing" numbers (1.4) and we shall prove that this is indeed the case.

Let $A_{k}$ Denote the set of numbers

$$
\left\{\begin{array}{l}
\mathrm{N}=\mathrm{u}_{\mathrm{k}_{1}}+\mathrm{u}_{\mathrm{k}_{2}}+\cdots+\mathrm{u}_{\mathrm{k}_{\mathrm{r}}},  \tag{1.7}\\
2 \leq \mathrm{k}=\mathrm{k}_{1}<\mathrm{k}_{2}<\cdots<\mathrm{k}_{\mathrm{r}}
\end{array}\right.
$$

and $r=1,2,3, \cdots$. We shall show that

$$
\begin{equation*}
A_{2 k+2}=a b^{k} a(\underset{\sim}{N}) \cup a b^{k} c(\underset{\sim}{N}) \quad(k \geq 0) \tag{1.8}
\end{equation*}
$$

and

$$
\begin{equation*}
A_{2 k+1}=b^{k} a(\underset{\sim}{\mathbb{N}}) \cup b^{k} c(\underset{\sim}{N}) \quad(k \geq 1) \tag{1.9}
\end{equation*}
$$

where N denotes the set of positive integers.
If N is given by (1.7), we define
(1.10)

Then we shall show that (1.11)

$$
\begin{gathered}
e(N)=u_{k_{r}-1}+u_{k_{r}-1}+\cdots+u_{k_{r}-1} \cdot \\
e(a(n))=n
\end{gathered}
$$

and
(1.12)

$$
e(b(n))=a(n)
$$

Clearly the domain of the function $c(n)$ is restricted to $a(\underset{\sim}{N}) \cup b(\underset{\sim}{N})$. However, since, as we shall see below, $(b(n)-2) \in a(\underset{\sim}{N})$ and
(1.13)

$$
\begin{gather*}
e(b(n)-2)=a(n) \\
e(c(n))=a(n) \tag{1.14}
\end{gather*}
$$

it is natural to define

Then $e(n)$ is defined for all $n$ and we show that $e(n)$ is monotone.
The functions $a, b, c$ satisfy various relations. In particular we have

$$
\begin{aligned}
& \mathrm{a}^{2}(\mathrm{n})=\mathrm{b}(\mathrm{n})-2=\mathrm{a}(\mathrm{n})+2 \mathrm{n}-2 \\
& \mathrm{ab}(\mathrm{n})=\mathrm{ba}(\mathrm{n})+2=2 \mathrm{a}(\mathrm{n})+\mathrm{b}(\mathrm{n}) \\
& \mathrm{ac}(\mathrm{n})=\mathrm{ca}(\mathrm{n})+2=2 \mathrm{a}(\mathrm{n})+\mathrm{c}(\mathrm{n}) \\
& \mathrm{cb}(\mathrm{n})=\mathrm{bc}(\mathrm{n})+2=2 \mathrm{a}(\mathrm{n})+3 \mathrm{c}(\mathrm{n})+2 .
\end{aligned}
$$

Moreover if we define

$$
\begin{equation*}
d(n)=a(n)+n \tag{1.15}
\end{equation*}
$$

then we have

$$
\begin{aligned}
\mathrm{da}(\mathrm{n}) & =2 \mathrm{~d}(\mathrm{n})-2 \\
\mathrm{db}(\mathrm{n}) & =4 \mathrm{~d}(\mathrm{n}) \\
\mathrm{dc}(\mathrm{n}) & =4 \mathrm{~d}(\mathrm{n})-2 .
\end{aligned}
$$

It follows from (1.11) and (1.12) that every positive integer N can be written in the form

$$
\begin{equation*}
N=u_{k_{1}}+u_{k_{2}}+\cdots+u_{k_{\mathrm{k}}} \tag{1.16}
\end{equation*}
$$

where now

$$
1 \leq \mathrm{k}_{1}<\mathrm{k}_{2}<\cdots<\mathrm{k}_{\mathrm{r}}
$$

Hence N is a "missing" number if and only if $\mathrm{k}_{1}=1, \mathrm{k}_{2}=2$.
The representation (1.16) is in general not unique. The numbers $a(n)$ are exactly those for which, in the representation (1.7), $k_{1}$ is even. Hence in (1.66) if we assume that $k_{1}$ is odd, the representation (1.16) is unique. We accordingly call this the canonical representation of N .

Returning to (1.15), we define the complementaryfunction $d^{\prime}(n)$ so that the sets $\{d(n)\}$, $\left\{d^{\prime}(n)\right\}$ constitute a disjoint partition of the positive integers. We shall show that
$d(n)=2 d^{\prime}(n)$.

| n | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 |
| :---: | :--- | :--- | :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| $\mathrm{~d}^{\mathrm{d}}$ | 1 | 3 | 4 | 5 | 7 | 9 | 11 | 12 | 13 | 15 | 16 | 17 | 19 | 20 | 21 | 23 |
| d | 2 | 6 | 8 | 10 | 14 | 18 | 22 | 24 | 26 | 30 | 32 | 34 | 38 | 40 | 42 | 46 |

Let $\delta(\mathrm{n})$ denote the number of $\mathrm{d}^{(\mathrm{k})} \leq \mathrm{n}$ and let $\delta^{\prime}(\mathrm{n})$ denote the number of $\mathrm{d}^{\prime}(\mathrm{k}) \leq \mathrm{n}$. We show that

$$
\begin{aligned}
& \delta(N)=\left[\frac{N}{2}\right]-\left[\frac{N}{4}\right]+\left[\frac{N}{8}\right]-\cdots \\
& \delta^{\prime}(N)=[N]-\left[\frac{N}{2}\right]+\left[\frac{N}{4}\right]-\cdots
\end{aligned}
$$

Finally, if N has the canonical representation (1.16) we define

$$
\begin{equation*}
\mathrm{f}(\mathrm{~N})=\sum_{\mathrm{i}=1}^{\mathrm{r}}(-1)^{\mathrm{k}_{\mathrm{i}}} \tag{1.18}
\end{equation*}
$$

It follows that

$$
\begin{equation*}
\mathrm{a}(\mathrm{~N})=2 \mathrm{~N}+\mathrm{f}(\mathrm{~N}) \tag{1.19}
\end{equation*}
$$

and

$$
\begin{equation*}
d(N)=a(N)+N=\sum_{i=1}^{r} 2^{k_{i}} \tag{1.20}
\end{equation*}
$$

so that there is a close connection with the binary representation of an integer.
Even though there is no "natural" irrationality associated with the sequence $\left\{u_{n}\right\}$, it is evident from the above summary that many of the results of the previous papers of this series $[2,3,4,5,6]$ have their counterpart in the present situation.

The material in the final two sections of the paper is not included in the above summary.

## 2. THE CANONICAL REPRESENTATION

As in the Introduction, we define the sequence $\left\{u_{n}\right\}$ by means of

$$
u_{0}=0, \quad u_{1}=1, \quad u_{n+1}=u_{n}+2 u_{n-1} \quad(n \geq 1)
$$

We first prove the following.
Theorem 2.1. Every positive integer N can be written uniquely in the form

$$
N=\epsilon_{1} u_{1}+\epsilon_{2} u_{2}+\cdots,
$$

where the $\epsilon_{i}=0$ or 1 and

$$
\begin{equation*}
\epsilon_{1}=\cdots=\epsilon_{\mathrm{k}-1}=0, \quad \epsilon_{\mathrm{k}}=1 \Rightarrow \mathrm{k} \text { odd } . \tag{2.2}
\end{equation*}
$$

Proof. The theorem can be easily proved by induction on $n$ as follows. Let $C_{2 n}$ consist of all sequences

$$
\left(\epsilon_{1}, \epsilon_{2}, \cdots, \epsilon_{2 n}\right) \quad\left(\epsilon_{i}=0 \text { or } 1\right)
$$

satisfying (2.2). Then the map

$$
\left(\epsilon_{1}, \epsilon_{2}, \cdots, \epsilon_{2 n}\right) \rightarrow \epsilon_{1} u_{1}+\epsilon_{2} u_{2}+\cdots+\epsilon_{2 n} u_{2 n}
$$

is $1-1$ and onto from $C_{2 n}$ to $\left[0, \cdots, u_{2 n+1}-1\right]$. Clearly $C_{2} \longrightarrow[0,1]$. Assuming that

$$
\mathrm{C}_{2 \mathrm{n}} \rightarrow\left[0, \cdots, u_{2 n+1}-1\right]
$$

we see that

$$
\begin{aligned}
C_{2 n+2} & \rightarrow\left[0, \cdots, u_{2 n+1}-1\right] \quad\left[u_{2 n+1}, \cdots, 2 u_{2 n+1}-1\right] \\
& \cup\left[u_{2 n+2}+1, \cdots, u_{2 n+1}+u_{2 n+2}-1\right] \\
& \cup\left[u_{2 n+1}+u_{2 n+2}, \cdots, 2 u_{2 n+1}+u_{2 n+2}-1\right] \\
& =\left[0, \cdots, u_{2 n+3}-1\right]
\end{aligned}
$$

since

$$
2 u_{2 n+1}-1=u_{2 n+2}
$$

If (2.2) is satisfied we call (2.1) the canonical representation of $N$.
In view of the above we have also
Theorem 2.2. If $N$ and $M$ are given canonically by

$$
N=\sum \epsilon_{i} u_{i}, \quad M=\sum \delta_{i} u_{i}
$$

then

$$
\begin{equation*}
N \leq M \text { if and only if } \sum \epsilon_{i} 2^{i} \leq \sum \delta_{i} 2^{i} \tag{2.3}
\end{equation*}
$$

Let N be given by (2.1) and define

$$
\begin{equation*}
\phi(\mathrm{N})=\sum \epsilon_{\mathrm{i}} 2^{\mathrm{i}} \tag{2.4}
\end{equation*}
$$

Note that since

$$
\begin{equation*}
u_{n}=\frac{1}{3}\left(2^{n}-(-1)^{n}\right) \tag{2.5}
\end{equation*}
$$

we have

$$
\begin{equation*}
N=\frac{1}{3}(\phi(N)-f(N)) \tag{2.6}
\end{equation*}
$$

where

$$
\begin{equation*}
\mathrm{f}(\mathrm{~N})=\epsilon(-1)^{\mathrm{i}} \epsilon_{\mathrm{i}} . \tag{2.7}
\end{equation*}
$$

Theorem 2.3. There are exactly $N$ numbers of the form $2^{k} K, k, K$ odd, less than or equal to $\phi(\mathrm{N})$.

Proof. The N numbers of the stated form are simply

$$
\phi(1), \phi(2), \cdots, \phi(\mathrm{N}) .
$$

If N is given canonically by

$$
N=\epsilon_{1} u_{1}+\epsilon_{2} u_{2}+\cdots
$$

we define
(2.8)

$$
a(n)=\epsilon_{1} u_{2}+\epsilon_{3} u_{3}+\cdots
$$

This is of course never canonical. Define

$$
\begin{equation*}
\mathrm{b}(\mathrm{n})=\mathrm{a}(\mathrm{~N})+2 \mathrm{~N}=\epsilon_{1} \mathrm{u}_{3}+\epsilon_{1} \mathrm{u}_{4}+\cdots \tag{2.9}
\end{equation*}
$$

The representation (2.9) is canonical.
Suppose $\epsilon_{2 k+1}$ is the first nonzero $\epsilon_{i}$ in the canonical representation of $N$. Then, since

$$
u_{1}+u_{2}+\cdots+u_{2 k+1}=u_{2 k+2},
$$

we see that $a(N)$ is given canonically by

$$
\begin{equation*}
\mathrm{a}(\mathrm{n})=\mathrm{u}_{1}+\mathrm{u}_{2}+\cdots+\mathrm{u}_{2 \mathrm{k}+1}+0 \cdot \mathrm{u}_{2 \mathrm{k}+2}+\epsilon_{2 \mathrm{k}+2} \mathrm{u}_{2 \mathrm{k}+3}+\cdots \tag{2.10}
\end{equation*}
$$

Let $c(N)=b(N)-1$. Then, since

$$
\mathrm{u}_{1}+\mathrm{u}_{2}+\cdots+\mathrm{u}_{2 \mathrm{k}+2}=\mathrm{u}_{2 \mathrm{k}+3}-1
$$

$c(N)$ is given canonically by
(2.11)

$$
\mathrm{c}(\mathrm{~N})=\mathrm{u}_{1}+\mathrm{u}_{2}+\cdots+\mathrm{u}_{2 \mathrm{k}+2}+0 \cdot \mathrm{u}_{2 \mathrm{k}+3}+\epsilon_{2 \mathrm{k}+2} \mathrm{u}_{2 \mathrm{k}+4}+\cdots
$$

We now state
Theorem 2.4. The three functions $a, b, c$ defined above are strictly monotone and their ranges $a(\mathbb{N}), b(\mathbb{N}), c(\mathbb{N})$ form a disjoint partition of $N$.

Proof. We have
(2.12)

$$
\phi(\mathrm{a}(\mathrm{~N})+1)=2 \phi(\mathrm{~N})+2
$$

and
(2.13)

$$
\phi(\mathrm{b}(\mathrm{~N}))=4 \phi(\mathrm{~N})
$$

Since $\phi$ is 1-1 and monotone, it follows that $a, b$, $c$ are monotone. By (2.10), $a(\underset{\sim}{N})$ consists of those $N$ whose canonical representations begin with an odd number of 1's; $b(\underset{\sim}{N})$ of those which begin with 0 ; and $c(\mathbb{N})$ of those which begin with an even number of 1 's. Hence all numbers are accounted for.

It is now clear that the functions $a, b, c$ defined above coincide with the $a, b, c$ defined in the Introduction.

The following two theorems are easy corollaries of the above.

Theorem 2.5. $c(\underset{\sim}{\mathbb{N}})$ is the set of integers that cannot be written as a sum of distinct $u_{i}$ with $i \geq 2$.

Thus the $c(\underset{\sim}{N})$ are the "missing" numbers of the Introduction.
Theorem 2.6. If $K \nsubseteq c(\underset{\sim}{N})$, then $K$ can be written uniquely as a sum of distinct $u_{i}$ with $\mathrm{i} \geq 2$.

## 3. RELATIONS INVOLVING $a, b$, AND $c$

We now define

$$
\mathrm{d}(\mathrm{~N})=\mathrm{a}(\mathrm{~N})+\mathrm{N} .
$$

Since

$$
u_{k}+u_{k+1}=2^{k}
$$

it follows at once from (2.4) and (2.8) that

$$
\begin{equation*}
\mathrm{d}(\mathrm{~N})=\phi(\mathrm{N}) \tag{3.1}
\end{equation*}
$$

Hence, by (2.6), we may write

$$
\begin{equation*}
2 \mathrm{~N}=\mathrm{a}(\mathrm{~N})-\mathrm{f}(\mathrm{~N}) \tag{3.2}
\end{equation*}
$$

Let $d^{\prime}$ denote the monotone function whose range is the complement of the range of $d$. Since the range of $\phi$ (that is, of $d$ ) consists of the numbers $2^{k} K$, with $k, K$ both odd, it follows that the range of $d^{\prime}$ consists of the numbers $2^{k} K$ with $k$ even and $K$ odd. We have therefore
(3.3) $\quad \mathrm{d}(\mathrm{N})=2 \mathrm{~d}^{\prime}(\mathrm{N})$.

Thus (2.12) and (2.13) become
(3.4)

$$
d(a+1)=2 d+2
$$

and
(3.5) $\quad d b=4 d$,
respectively.
From (2.10) we obtain
(3.6)

$$
\mathrm{da}=2 \mathrm{~d}-2
$$

and
(3.7)

$$
d^{\prime} a=d-1
$$

Theorem 3.1. We have
(3.11)
$a^{2}(N)=b(N)-2=a(N)+2 N-2$
$a b(N)=b a(N)+2=2 a(N)+b(N)$
$a c(N)=c a(N)+2=2 a(N)+c(N)$
$\mathrm{cb}(\mathrm{N})=\mathrm{bc}(\mathrm{N})+2=2 \mathrm{a}(\mathrm{N})+3 \mathrm{c}(\mathrm{N})$
(3.12)
$\mathrm{da}(\mathrm{N})=2 \mathrm{~d}(\mathrm{~N})-2$
$\mathrm{db}(\mathrm{N})=4 \mathrm{~d}(\mathrm{~N})$
$\mathrm{dc}(\mathrm{N})=4 \mathrm{~d}(\mathrm{~N})-2$.

Proof. The first four formulas follow from the definitions. For example if

$$
\mathrm{N}=\mathrm{u}_{2 \mathrm{k}+1}+\epsilon_{2 \mathrm{k}+2} \mathrm{u}_{2 \mathrm{k}+2}+\cdots,
$$

then

$$
\mathrm{a}(\mathrm{~N})=1 \cdot \mathrm{u}_{1}+1 \cdot \mathrm{u}_{2}+\cdots+1 \cdot \mathrm{u}_{2 \mathrm{k}+1}+\epsilon_{2 \mathrm{k}+2} \mathrm{u}_{2 \mathrm{k}+3}+\cdots
$$

and

$$
\begin{aligned}
\mathrm{a}^{2}(\mathrm{~N}) & =1 \cdot \mathrm{u}_{2}+\cdots+1 \cdot \mathrm{u}_{2 \mathrm{k}+2}+\epsilon_{2 \mathrm{k}+2} u_{2 \mathrm{k}+4}+\cdots \\
& =u_{2 \mathrm{k}+3}-2+\epsilon_{2 \mathrm{k}+2} u_{2 \mathrm{k}+4}+\cdots \\
& =\mathrm{b}(\mathrm{~N})-2
\end{aligned}
$$

Formula (3.12) is the same as (3.6) while (3.13) and (3.14) follow from the formulas for $a b$ and ac.

In view of Theorem 2.6, every

```
N}\ina(\mathbb{N})\cupb(N
```

can be written uniquely in the form

$$
\begin{equation*}
\mathrm{N}=\delta_{2} \mathrm{u}_{2}+\delta_{3} \mathrm{u}_{3}+\cdots \tag{3.15}
\end{equation*}
$$

with $\delta_{2}=0,1$. We define $A_{k}$ as the set of $N$ for which $\delta_{k}$ is the first nonzero $\delta_{i}$. Theorem 3.2. We have

$$
\begin{array}{ll}
A_{2 k+2}=a b^{k} a(\underset{\sim}{N}) \cup a b^{k} c(\underset{\sim}{N}) & (k \geq 0) \\
A_{2 k+1}=b^{k} a(\underset{\sim}{N}) \cup b^{k} c(\underset{\sim}{N}) & (k \geq 1) \tag{3.17}
\end{array}
$$

Proof. By (2.9), (2.10) and (2.11), the union

$$
a(\mathbb{N}) \cup c(\mathbb{N})
$$

consists of those K for which

$$
\epsilon_{1}=\epsilon_{1}(K)=1
$$

Hence, applying a, we have

$$
\mathrm{A}_{2}=\mathrm{a}^{2}(\underset{\sim}{\mathbb{N}}) \cup \mathrm{ac}(\mathbb{N})
$$

and, applying $b$,

$$
\mathrm{A}_{3}=\mathrm{ba}(\underset{\sim}{\mathbb{N}}) \cup \mathrm{bc}(\underset{\sim}{\mathbb{N}}) .
$$

Continuing in this way, it is clear that we obtain the stated results.
Theorem 3.2 admits of the following refinement.
Theorem 3.3. We have

$$
\begin{align*}
& \mathrm{ab}^{\mathrm{k}} \mathrm{a}(\underset{\sim}{\mathbb{N}})=\left\{\mathrm{N} \in \mathrm{~A}_{2 \mathrm{k}+2} \mid \mathrm{N}=\mathrm{ab}^{\mathrm{k}} \mathrm{a}(\mathrm{n}) \equiv \mathrm{n}(\bmod 2)\right\}  \tag{3.17}\\
& \mathrm{ab}^{\mathrm{k}} \mathrm{c}(\underset{\sim}{\mathbb{N}})=\left\{\mathrm{N} \in \mathrm{~A}_{2 \mathrm{k}+2} \mid \mathrm{N}=\mathrm{ab}^{\mathrm{k}} \mathbf{c}(\mathrm{n}) \equiv \mathrm{n}+1(\bmod 2)\right\}  \tag{3.18}\\
& \mathrm{b}^{\mathrm{k}} \mathrm{a}(\underset{\sim}{\mathrm{~N}})=\left\{\mathrm{N} \in \mathrm{~A}_{2 \mathrm{k}+1} \mid \mathrm{N}=\mathrm{b}^{\mathrm{k}} \mathrm{a}(\mathrm{n}) \equiv \mathrm{n}(\bmod 2)\right\} \tag{3.19}
\end{align*}
$$

$$
\begin{equation*}
\mathrm{b}^{\mathrm{k}} \mathrm{c}(\underset{\sim}{\mathrm{~N}})=\left\{\mathrm{N} \in \mathrm{~A}_{2 \mathrm{k}+1} \mid \mathrm{N}=\mathrm{b}^{\mathrm{k}} \mathrm{c}(\mathrm{n}) \equiv \mathrm{n}+1(\bmod 2)\right\} \tag{3.20}
\end{equation*}
$$

Proof. The theorem follows from Theorem 3.2 together with the observation

$$
\begin{equation*}
a(n) \equiv b(n) \equiv n, \quad c(n) \equiv n+1(\bmod 2) \tag{3.21}
\end{equation*}
$$

Let

$$
N \in a(\mathbb{N}) \cup b(\underset{\sim}{\mathbb{N}})
$$

so that (3.15) is satisfied. We define

$$
\begin{equation*}
e(N)=\delta_{2} u_{1}+\delta_{3} u_{2}+\cdots \tag{3.21}
\end{equation*}
$$

Then from the definition of $a$ and $b$ we see that
(3.22)

$$
e(a(n))=n
$$

and
(3.23)

$$
e(b(n))=a(n)
$$

Since

$$
a^{2}(n)=b(n)-2<c(n)<b(n),
$$

we define
(3.24)

$$
e(c(n))=a(n)
$$

Thus $e(n)$ is now defined for all $n$.

| n | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| e | 1 | 1 | 1 | 2 | 3 | 4 | 4 | 4 | 5 | 5 | 5 | 6 | 6 | 6 | 7 | 8 | 9 | 9 | 9 | 10 |
| n | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 | 32 | 33 | 34 | 35 | 36 | 37 | 38 | 39 | 40 |
| e | 11 | 12 | 12 | 12 | 13 | 14 | 15 | 15 | 15 | 16 | 16 | 16 | 17 | 17 | 17 | 18 | 19 | 20 | 20 | 20 |

Theorem 3.4. The function $e$ is monotone. Indeed $e(n)=e(n-1)$ if and only if

$$
\mathrm{n} \in \mathrm{~b}(\underset{\sim}{\mathbb{N}}) \cup \mathrm{c}(\underset{\sim}{\mathbb{N}})
$$

Otherwise $(\mathrm{n} \in \mathrm{a}(\underset{\sim}{\mathrm{N}})$ )

$$
e(n)=e(n-1)+1
$$

Proof. We have already seen that

$$
e \mathrm{~b}(\mathrm{n})=\mathrm{ec}(\mathrm{n})=\mathrm{ec}(\mathrm{n})-1=\mathrm{a}(\mathrm{n})
$$

Thus it remains to show that

$$
\begin{equation*}
e(a(n))=e(a(n)-1)+1 \tag{3.25}
\end{equation*}
$$

Let

$$
\mathrm{n}=\mathrm{u}_{2 \mathrm{k}+1}+\epsilon_{2 \mathrm{k}+2} \mathrm{u}_{2 \mathrm{k}+2}+\cdots
$$

be the canonical representation of $n$. Then

$$
\mathrm{a}(\mathrm{n})=\mathrm{u}_{2 \mathrm{k}+2}+\epsilon_{2 \mathrm{k}+2} \mathrm{u}_{2 \mathrm{k}+3}+\cdots
$$

Since

$$
u_{2 k+2}-1=u_{2}+u_{3}+u_{4}+\cdots+u_{2 k+1}
$$

we get

$$
\mathrm{a}(\mathrm{n})-1=\mathrm{u}_{2}+\mathrm{u}_{3}+\cdots+\mathrm{u}_{2 \mathrm{k}+1}+\epsilon_{2 \mathrm{k}+2} \mathrm{u}_{2 \mathrm{k}+3}+\cdots
$$

It follows that

$$
\begin{aligned}
e(a(n)-1) & =u_{1}+u_{2}+\cdots+u_{2 k}+\epsilon_{2 k+2} u_{2 k+2}+\cdots \\
& =\left(u_{2 k+1}-1\right)+\epsilon_{2 k+2} u_{2 k+2}+\cdots \\
& =n-1
\end{aligned}
$$

This evidently proves (3.25).
Theorem 3.5. We have

$$
\left\{\begin{array}{l}
a(n+1)=a(n)+3  \tag{3.26}\\
a(n+1)=a(n)+1
\end{array} \quad(n \in a(\mathbb{N}))\right.
$$

Proof. Formula (3.4) is evidently equivalent to

$$
\begin{equation*}
a(a(n)+1)=b(n)+1 \tag{3.27}
\end{equation*}
$$

By (3.8)

$$
a^{2}(n)=b(n)-2=c(n)-1
$$

so that we have the sequence of consecutive integers

$$
\begin{equation*}
a^{2}(n), \quad c(n), \quad b(n), \quad a \quad a(n)+1 . \tag{3.28}
\end{equation*}
$$

On the other hand, by (3.9) and (3.10)

$$
a b(n)=a c(n)+1
$$

Finally, since

$$
b(n)+1 \in a(n)
$$

we have, by (3.28),

$$
\begin{aligned}
a(b(n)+1) & =a^{2}(a(n)+1)=b a(n)+1-2 \\
& =a(a(n)+1)+2 a(n) \\
& =2 a(n)+b(n)+1 \\
& =a b(n)+1
\end{aligned}
$$

This completes the proof of the theorem.
If we let $\alpha(\mathrm{n})$ denote the number of $\mathrm{a}(\mathrm{k})<\mathrm{n}$, it follows at once from Theorem 3.5 that

$$
\begin{equation*}
\mathrm{a}(\mathrm{n})=\mathrm{n}+2 \alpha(\mathrm{n}) \quad(\mathrm{n} \geq 1) \tag{3.29}
\end{equation*}
$$

This is equivalent to

$$
\mathrm{d}^{\prime}(\mathrm{n})=\mathrm{n}+\alpha(\mathrm{n})
$$

We shall now show that

$$
\begin{equation*}
\alpha(\mathrm{n}+1)=\mathrm{e}(\mathrm{n}) \tag{3.31}
\end{equation*}
$$

Let $n \in a(\underset{\sim}{N}) \cup b(\underset{\sim}{N})$. Then

$$
\mathrm{n}=\mathrm{u}_{\mathrm{k}}=\epsilon_{\mathrm{k}+1} \mathrm{u}_{\mathrm{k}+1}+\cdots \quad(\mathrm{k} \geq 2)
$$

and

$$
\mathrm{e}(\mathrm{n})=\mathrm{u}_{\mathrm{k}-1}+\epsilon_{\mathrm{k}+1} \mathrm{u}_{\mathrm{k}}+\cdots
$$

Also

$$
\mathrm{n}+1=\mathrm{u}_{1}+\mathrm{u}_{\mathrm{k}}+\epsilon_{\mathrm{k}+1} \mathrm{u}_{\mathrm{k}+1}+\cdots \quad \text { (canonical) }
$$

so that

$$
\mathrm{a}(\mathrm{n}+1)=\mathrm{u}_{2}+\mathrm{u}_{\mathrm{k}+1}+\epsilon_{\mathrm{k}+1} \mathrm{u}_{\mathrm{k}+2}+\cdots
$$

It follows that

$$
\begin{equation*}
\mathrm{a}(\mathrm{n}+1)-2 \mathrm{e}(\mathrm{n})=\mathrm{n}+1 \quad(\mathrm{n} \notin \mathrm{c}(\mathbb{N})) \tag{3.32}
\end{equation*}
$$

If $n \in c(\underset{\sim}{N})$ we have $e(n)=e(n+1)$. Since $n+1 \in b(\mathbb{N})$, we may use (3.32). Thus

$$
2 e(n)=2 e(n+1)=a(n+2)-(n+2)=a(n+1)-(n+1)
$$

by (3.26). Hence

$$
\mathrm{a}(\mathrm{n}+1)-2 \mathrm{e}(\mathrm{n})=\mathrm{n}+1
$$

for all n . This is evidently equivalent to (3.31).
This proves
Theorem 3.6. The number of $\mathrm{a}(\mathrm{k}) \leq \mathrm{n}$ is equal to $\mathrm{e}(\mathrm{n})$. Moreover

$$
\begin{equation*}
a(n)=n+2 e(n-1) \quad(n>1) \tag{3.33}
\end{equation*}
$$

A few special values of $a(n)$ may be noted:

$$
\begin{array}{cc}
\mathrm{a}\left(2^{2 \mathrm{k}-1}\right)=2^{2 \mathrm{k}} & (\mathrm{k} \geq 1) \\
\mathrm{a}\left(2^{2 \mathrm{k}}\right)=2^{2 \mathrm{k}+1}-2 & (\mathrm{k} \geq 1) \\
\mathrm{a}\left(2^{2 \mathrm{k}-1}-2\right)=2^{2 \mathrm{k}}-4 & (\mathrm{k}>1) \\
\mathrm{a}\left(2^{2 \mathrm{k}}-2\right)=2^{2 \mathrm{k}+1}-6 & (\mathrm{k}>2) .
\end{array}
$$

## 4. COMPARISON WITH THE BINARY REPRESENTATION

If N is given in its binary representation

$$
\begin{equation*}
\mathrm{N}=\gamma_{0}+\gamma_{1} \cdot 2+\gamma_{2} \cdot 2^{2}+\cdots \tag{4.1}
\end{equation*}
$$

where $\gamma_{1}=0$ or 1 , we define

$$
\delta(\mathrm{N})=\gamma_{0} u_{0}+\gamma_{1} u_{1}+\gamma_{2} u_{2}+\cdots
$$

and
(4.3)

$$
(N)=\sum_{i} \gamma_{i}(-1)^{\mathrm{i}}
$$

Then we have

$$
\delta(\mathrm{d}(\mathrm{~N}))=\mathrm{N}
$$

and
(4.5)

$$
\chi(\mathrm{d}(\mathrm{~N}))=\mathrm{f}(\mathrm{~N})
$$

A simple computation leads to
(4.6) $\delta(N)=\left[\frac{N}{2}\right]-\left[\frac{N}{4}\right]+\left[\frac{N}{8}\right]-\cdots$.

Let
(4.7)

$$
\delta^{\prime}(\mathrm{N})=\mathrm{N}-\left[\frac{\mathrm{N}}{2}\right]+\left[\frac{\mathrm{N}}{4}\right]-\cdots
$$

so that
(4.8)

$$
\delta(\mathrm{N})+\delta \mathrm{r}(\mathrm{~N})=\mathrm{N} .
$$

Theorem 4.1. The number of $d(k) \leq n$ is equal to $\delta(N)$. The number of $d^{\prime}(k) \leq n$ is equal to $\delta(\mathrm{N})$.

Proof. Since $\delta$ is monotone, we have $d(k) \leq n$ if and only if

$$
\mathrm{k}=\delta \mathrm{d}(\mathrm{k}) \quad \leq \delta(\mathrm{n})
$$

Hence, in view of (4.8), the theorem is proved.
We have seen in Section 3 that if N has the canonical representation

$$
N=\epsilon_{1} u_{1}+\epsilon_{2} u_{2}+\cdots
$$

then
(4.9)

$$
\mathrm{a}(\mathrm{~N})-2 \mathrm{~N}=\mathrm{f}(\mathrm{~N})
$$

where

$$
\mathrm{f}(\mathrm{~N})=\sum_{\mathrm{i}}(-1)^{\mathrm{i}} \epsilon_{\mathrm{i}} .
$$

It follows that

$$
\begin{equation*}
\mathrm{d}(\mathrm{~N})=\mathrm{a}(\mathrm{~N})+\mathrm{N}=\sum_{\mathrm{i}} \epsilon_{\mathrm{i}} \cdot 2^{\mathrm{i}} \tag{4.10}
\end{equation*}
$$

Replacing $N$ by $d(N), d^{\prime}(N)$ in (4.9), we get

$$
\begin{equation*}
\mathrm{a}(\mathrm{~d}(\mathrm{~N}))-2 \mathrm{~d}(\mathrm{~N})=\mathrm{f}(\mathrm{~d}(\mathrm{~N})) \tag{4.11}
\end{equation*}
$$

and
(4.12)

$$
\mathrm{a}\left(\mathrm{~d}^{\mathrm{r}}(\mathrm{~N})\right)-2 \mathrm{~d}^{\prime}(\mathrm{N})=\mathrm{f}(\mathrm{~d}(\mathrm{~N}))
$$

Theorem 4.2. The function $f(d)$ takes on every even value (positive, negative or zero) infinitely often. The function $f\left(d^{\prime}\right)$ takes on every odd value (positive or negative) infinitely often.

Proof. Consider the number

Clearly

$$
\begin{aligned}
\mathrm{N} & =\mathrm{u}_{1}+\mathrm{u}_{3}+\mathrm{u}_{5}+\cdots+\mathrm{u}_{2 \mathrm{k}-1} \\
& =\frac{1}{3}\left(2^{1}+1\right)+\frac{1}{3}\left(2^{3}+1\right)+\cdots+\frac{1}{3}\left(2^{2 \mathrm{k}-1}+1\right) \\
& =\frac{1}{3}\left(\frac{2}{3}\left(2^{2 \mathrm{k}}-1\right)+\mathrm{k}\right) .
\end{aligned}
$$

(4.13)

$$
N \equiv 2(\bmod 4)
$$

if and only if

$$
\begin{equation*}
\mathrm{k} \equiv 0(\bmod 4) \tag{4.14}
\end{equation*}
$$

It follows from (4.13) that $N \in d(\underset{\sim}{N})$. Also it is evident that

$$
\begin{equation*}
\mathrm{f}(\mathrm{~N})=-\mathrm{k}, \quad \mathrm{k} \equiv 0(\bmod 4) \tag{4.15}
\end{equation*}
$$

In the next place the number

$$
\begin{aligned}
\mathrm{N} & =\mathrm{u}_{3}+\mathrm{u}_{5}+\cdots+\mathrm{u}_{2 \mathrm{k}+1} \\
& =\frac{1}{3}\left(2^{3}+1\right)+\frac{1}{3}\left(2^{5}+1\right)+\cdots+\frac{1}{3}\left(2^{2 \mathrm{k}+1}+1\right) \\
& \equiv 3 \mathrm{k} \quad(\bmod 8) .
\end{aligned}
$$

Hence for $k \equiv 2(\bmod 4)$, we have $N \equiv 2(\bmod 4)$ and so as above $N \in d(\mathbb{N})$. Also it is evident that (4.15) holds in this case also.

Now consider

$$
\begin{aligned}
N & =u_{1}+u_{2}+u_{4}+u_{6}+\cdots+u_{2 k} \\
& =1+\frac{1}{3}\left(2^{2}-1\right)+\frac{1}{3}\left(2^{4}-1\right)+\cdots+\frac{1}{3}\left(2^{2 \mathrm{k}}-1\right) \\
& \equiv 1+\mathrm{k} \quad(\bmod 4) .
\end{aligned}
$$

Thus for k odd, $\mathrm{N} \in \mathrm{d}(\underset{\sim}{\mathrm{N}})$. Also it is clear that

$$
f(N)=k-1 .
$$

This evidently proves the first half of the theorem.
To form the second half of the theorem we first take

$$
N=u_{1}+u_{3}+u_{5}+\cdots+u_{2 k-1}
$$

Then

$$
\mathrm{N} \equiv \mathrm{k} \quad(\bmod 2)
$$

Thus for $k$ odd, $N \in d^{\prime}(\underset{\sim}{N})$. Moreover

$$
\begin{equation*}
\mathrm{f}(\mathrm{~N})=-\mathrm{k} \tag{4.16}
\end{equation*}
$$

Next for

$$
N=u_{1}+u_{2}+u_{4}+u_{6}+\cdots+u_{2 k}+u_{2 k+2}
$$

we again have

$$
N \equiv k \quad(\bmod 2)
$$

so that $N \in d^{\prime}(\underset{\sim}{N})$ for $k$ odd. Clearly

$$
\begin{equation*}
\mathrm{f}(\mathrm{~N})=\mathrm{k} \tag{4.17}
\end{equation*}
$$

This completes the proof of the theorem.
As an immediate corollary of Theorem 4.2 we have
Theorem 4.3. The commutator

$$
\operatorname{ad}(\mathrm{N})-\mathrm{da}(\mathrm{~N})=\mathrm{fd}(\mathrm{~N})+2
$$

takes on every even value infinitely often. Also the commutator

$$
\operatorname{ad}^{\prime}(\mathrm{N})-\mathrm{d}^{\prime} \mathrm{a}(\mathrm{~N})=\mathrm{fd}^{\prime}(\mathrm{N})+1
$$

takes on every even value infinitely often.

## 5. WORDS

By a word function, or briefly, word, is meant a function of the form

$$
\begin{equation*}
w=a^{\alpha} b^{\beta} c^{\gamma} a^{\alpha^{\prime}} b^{\beta^{\prime}} c^{\gamma^{\prime}} \ldots, \tag{5.1}
\end{equation*}
$$

where the exponents are arbitrary non-negative integers.
Theorem 5.1. Every word function $w(n)$ can be linearized, that is

$$
\begin{equation*}
w(n)=A_{w} a(n)+B_{w} n-C_{w} \quad\left(A_{w}>0\right) \tag{5.2}
\end{equation*}
$$

where $A_{w}, B_{w}, C_{w}$ are independent of $n$. Moreover the representation (5.2) is unique.
Proof. The representation (5.2) follows from the relations

$$
\left\{\begin{array}{l}
a^{2}(n)=a(n)+2 n-2  \tag{5.3}\\
a b(n)=2 a(n)+b(n)=3 a(n)+2 n \\
a c(n)=2 a(n)+c(n)=3 a(n)+2 n-1
\end{array}\right.
$$

If we assume a second representation (5.2) it follows that $a(n)$ is a linear function of n. This evidently contradicts Theorem 3.5.

Theorem 5.2. For any word $w$, the coefficient $B_{w}$ in (5.2) is even. Hence the function d is not a word.

Proof. Repeated application of (5.3).
Remark. If we had defined words as the set of functions of the form

$$
\begin{equation*}
a^{\alpha} b^{\beta} c^{\gamma} d^{\delta} \cdots, \tag{5.4}
\end{equation*}
$$

then, in view of Theorem 4.3, we would not be able to assert the extended form of Theorem 5.1.

Combining (5.3) with (5.2), we get the following recurrences for the coefficients $A_{w}$, $\mathrm{B}_{\mathrm{w}}, \mathrm{C}_{\mathrm{w}}$ :

$$
\left\{\begin{array}{l}
A_{w a}=A_{w}+B_{w}  \tag{5.5}\\
B_{w a}=2 A_{w} \\
C_{w a}=2 A_{w}+C_{w}
\end{array}\right.
$$

$$
\left\{\begin{array}{l}
A_{w b}=3 A_{w}+B_{w}  \tag{5.6}\\
B_{w b}=2 A_{w}+2 B_{w} \\
C_{w b}=C_{w}
\end{array}\right.
$$

$$
\left\{\begin{array}{l}
A_{w c}=3 A_{w}+B_{w} \\
B_{w c}=2 A_{w}+2 B_{w} \\
C_{w c}=A_{w}+B_{w}+C_{w} .
\end{array}\right.
$$

In particular we find that

$$
\begin{gather*}
a^{k}(n)=u_{k} a(n)+2 u_{k-1} n-\left(u_{k+1}-1\right),  \tag{5.8}\\
a b^{k}(n)=u_{2 k+1} a(n)+\left(u_{2 k+1}-1\right) n,  \tag{5.9}\\
a c^{k}(n)=u_{2 k+1} a(n)+\left(u_{2 k+1}-1\right) n-\frac{1}{3}\left(4 u_{2 k}-k\right)  \tag{5.10}\\
b^{k}(n)=u_{2 k} a(n)+\left(u_{2 k}+1\right) n,  \tag{5.11}\\
a^{k} b^{j}(n)=u_{k+2 j} a(n)+2 u_{k+2 j-1} n-\left(u_{k+1}-1\right)  \tag{5.12}\\
b^{j} a^{k}(n)=u_{k+2 j} a(n)+2 u_{k+2 j-1} n-\left(u_{k+2 j+1}-u_{2 j+1}\right),  \tag{5.13}\\
a^{k} b^{j}(n)-b^{j} a^{k}(n)=u_{k+2 j+1}-u_{k+1}-u_{2 j+1}+1  \tag{5.14}\\
=\frac{2}{3}\left(2^{k}-1\right)\left(2^{2 j}-1\right)
\end{gather*}
$$

We shall now evaluate $A_{w}$ and $B_{w}$ explicitly. For $w$ as given by (5.1) we define the weight of $w$ by means of

$$
\mathrm{p}=\mathrm{p}(\mathrm{w})=\alpha+2 \beta+2 \gamma+\alpha^{\prime}+2 \beta^{\prime}+2 \gamma^{\prime}+\ldots
$$

We shall show that

$$
\begin{equation*}
A_{w}=u_{p}, \quad B_{w}=2 u_{p-1} \tag{5.16}
\end{equation*}
$$

The proof is by induction on p . For $\mathrm{p}=1$, (5.16) obviously holds. Assume that (5.16) holds up to and including the value p. By the inductive hypothesis, (5.5), (5.6), (5.7) become

$$
\begin{gather*}
\left\{\begin{array}{l}
A_{w a}=A_{p}+B_{p}=u_{p}+2 u_{p-1}=u_{p+1} \\
B_{w a}=2 A_{p}=2 u_{p}
\end{array}\right.  \tag{5.17}\\
\left\{\begin{array}{l}
A_{w b}=A_{w c}=3 A_{p}+B_{p}=3 u_{p}+2 u_{p-1}=u_{p+2} \\
B_{w p}=B_{w c}=2 A_{p}+2 B_{p}=2 u_{p}+2 u_{p-1}=u_{p+1}
\end{array} .\right.
\end{gather*}
$$

This evidently completes the induction.
As for $C_{w}$, we have

$$
\left\{\begin{array}{l}
C_{w a}=2 u_{p}+C_{w}  \tag{5.19}\\
C_{w b}=C_{w} \\
C_{w c}=u_{p+1}+C_{w}
\end{array}\right.
$$

Unlike $A_{w}$ and $B_{w}$, the coefficient $C_{w}$ is not a function of the weight alone. For example

$$
\begin{array}{lll}
\mathrm{C}_{\mathrm{a}^{2}}=2, & \mathrm{C}_{\mathrm{b}}=0, & \mathrm{C}_{\mathrm{c}}=1, \\
\mathrm{C}_{\mathrm{a}^{3}}=4, & \mathrm{C}_{\mathrm{ab}}=0, & \mathrm{C}_{\mathrm{ac}}=1 .
\end{array}
$$

Repeated application of (5.19) gives

$$
\begin{aligned}
& C_{a^{k}}=2\left(u_{1}+u_{2}+\cdots+u_{k-1}\right)=u_{k+1}-1 \\
& C_{b^{k}}=0 \\
& C_{c^{k}}=u_{1}+\cdots+u_{k}=\frac{1}{2}\left(u_{k+2}-1\right)
\end{aligned}
$$

of which the first two agree with (5.8) and (5.11).
We may state
Theorem 5.3. If $w$ is a word of weight $p$, then

$$
\begin{equation*}
w(n)-u_{p} a(n)+2 u_{p-1} n-C w_{w}, \tag{5.20}
\end{equation*}
$$

where $C_{w}$ can be evaluated by means of (5.19). If $w, w^{\prime}$ are any words of equal weight, then

$$
\begin{equation*}
\mathrm{w}(\mathrm{n})-\mathrm{w}^{\prime}(\mathrm{n})=\mathrm{C}_{\mathrm{w}^{\prime}}-\mathrm{C}_{\mathrm{w}} . \tag{5.21}
\end{equation*}
$$

Theorem 5.4. For any word w, the representation

$$
w=a^{\alpha} b^{\beta} c^{\gamma} a^{\alpha^{\prime}}{ }^{\beta^{\prime}} c^{\gamma^{\prime}} \ldots
$$

is unique.
Proof. The theorem is a consequence of the following observation. If $u, v$ are any words, then it follows from any one of

$$
\text { ua }=\mathrm{va}, \quad \mathrm{ub}=\mathrm{vb}, \quad \mathrm{uc}=\mathrm{vc}
$$

that $\mathrm{u}=\mathrm{v}$.
Theorem 5.5. The words $u, v$ satisfy $u v=v u$ if and only if there is a word $w$ such that

$$
u=w^{r}, \quad v=w^{s},
$$

where $r, s$ are non-negative integers.
Theorem 5.6. In the notation of Theorem 5.3, $C_{w}=C_{w}^{\prime}$ if and only if $w=w^{\prime}$. Remark. It follows from (5.20) that no multiple of $\mathrm{d}^{\prime}(\mathrm{n})$ is a word function.

## 6. GENERATING FUNCTIONS

Put

$$
\begin{equation*}
A(x)=\sum_{n=1}^{\infty} x^{a(n)}, \quad B(x)=\sum_{n=1}^{\infty} x^{b(n)}, \quad C(x)=\sum_{n=1}^{\infty} x^{c(n)} \tag{6.1}
\end{equation*}
$$

and

$$
\begin{equation*}
D(x)=\sum_{n=1}^{\infty} x^{d(n)}, \quad D_{1}(x)=\sum_{n=1}^{\infty} x^{d^{\prime}(n)}, \tag{6.2}
\end{equation*}
$$

where of course $|x|<1$. Then clearly

$$
\begin{equation*}
A(x)+B(x)+C(x)=\frac{x}{1-x} \tag{6.3}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathrm{D}(\mathrm{x})+\mathrm{D}_{1}(\mathrm{x})=\frac{\mathrm{x}}{1-\mathrm{x}} \tag{6.4}
\end{equation*}
$$

Since

$$
\mathrm{b}(\mathrm{n})=\mathrm{c}(\mathrm{n})+1, \quad \mathrm{~d}(\mathrm{n})=2 \mathrm{~d}^{\prime}(\mathrm{n}),
$$

( 6.3 ) and ( 6.4 ) reduce to

$$
\begin{equation*}
A(x)+(1+x) C(x)=\frac{x}{1-x} \tag{6.5}
\end{equation*}
$$

and

$$
\begin{equation*}
D_{1}(x)+D_{1}\left(x^{2}\right)=\frac{x}{1-x} \tag{6.6}
\end{equation*}
$$

respectively.

It follows from (6.6) that

$$
\begin{aligned}
D_{1}(x) & =\frac{x}{1-x}-\frac{x^{2}}{1-x^{2}}+\frac{x^{4}}{1-x^{4}}-\cdots \\
& =\sum_{k=0}^{\infty}(-1)^{k} \sum_{r=1}^{\infty} x^{2^{k} r} \\
& =\sum_{n=1}^{\infty} x^{n} \sum_{2^{k} r=n}(-1)^{k},
\end{aligned}
$$

so that

$$
d^{\prime}(n)=\sum_{2^{k} r=n}(-1)^{k} .
$$

This is equivalent to the result previously obtained that

$$
\mathrm{d}^{\prime}(\underset{\sim}{\mathbb{N}})=\left\{2^{\mathrm{m}_{\mathrm{M}}} \mid \mathrm{m} \text { even, } \quad \mathrm{M} \text { odd }\right\} .
$$

Theorem 6.1. Each of the functions $\mathrm{A}(\mathrm{x}), \mathrm{B}(\mathrm{x}), \mathrm{C}(\mathrm{x}), \mathrm{D}(\mathrm{x}), \mathrm{D}_{1}(\mathrm{x})$ has the unit circle as a natural boundary.

Proof. It will evidently suffice to prove the theorem for $A(x)$ and $D_{1}(x)$. We consider first the function $D_{1}(x)$.

To begin with, $D_{1}(x)$ has a singularity at $x=1$. Hence, by (6.6), $D_{1}(x)$ has a singularity at $\mathrm{x}=-1$. Replacing x by $\mathrm{x}^{2}$, (6.6) becomes

$$
D_{1}\left(x^{2}\right)+D_{1}\left(x^{4}\right)=\frac{x^{2}}{1-x^{2}}
$$

We infer that $D_{1}(x)$ has singularities at $x= \pm i$. Continuing in this way we show that $D_{1}(x)$ has singularities at

$$
\mathrm{x}=\mathrm{e}^{2 \mathrm{k} \pi \mathrm{i} / 2^{\mathrm{n}}} \quad\left(\mathrm{k}=1,3,5, \cdots, 2^{\mathrm{n}}-1 ; \mathrm{n}=1,2,3, \cdots\right)
$$

This proves that $D_{1}(x)$ cannot be continued analytically across the unit circle.
In the next place if the function

$$
f(x)=\sum_{n=1}^{\infty} c_{n} x^{n}
$$

where the $c_{n}=0$ or 1 , can be continued across the unit circle, then [1, p. 315]

$$
f(x)=\frac{P(x)}{1-x^{k}}
$$

where $P(x)$ is a polynomial and $k$ is some positive integer. Hence
(6.7)
$c_{n}=c_{n-k}$
( $\mathrm{n} \geq \mathrm{n}_{0}$ ).

Now assume that $A(x)$ can be continued across the unit circle. Then by (6.7), there exists an integer $k$ such that

$$
\mathrm{a}(\mathrm{n})=\mathrm{a}\left(\mathrm{n}_{1}\right)+\mathrm{k} \quad\left(\mathrm{n}>\mathrm{n}_{0}\right),
$$

where $n_{1}$ depends on $n$. It follows that

$$
a(n)=a(n-r)+k \quad\left(n>n_{0}\right)
$$

for some fixed r. This implies
(6.9) $d(n)=a(n-r)+k+r \quad\left(n>u_{0}\right)$.

However (6.9) contradicts the fact that $D(x)=D_{1}\left(x^{2}\right)$ cannot be continued across the unit circle.

Theorem 6.2. Let $w(n)$ be an arbitrary word function of positive weight and put

$$
\begin{equation*}
\mathrm{F}_{\mathrm{w}}(\mathrm{x})=\sum_{\mathrm{n}=1}^{\infty} \mathrm{x}^{\mathrm{w}(\mathrm{n})} \tag{6.10}
\end{equation*}
$$

Then $F_{w}(x)$ cannot be continued across the unit circle.
Proof. Assume that $\mathrm{F}_{\mathrm{w}}(\mathrm{x})$ does admit of analytic continuation across the unit circle. Then there exist integers $r, k$ such that

$$
\mathrm{w}(\mathrm{n})=\mathrm{w}(\mathrm{n}-\mathrm{r})+\mathrm{s} \quad\left(\mathrm{n}>\mathrm{n}_{0}\right) .
$$

By (5.2) this becomes

$$
A_{w} a(n)+B_{w} r=A_{w}(n-r)+k
$$

This implies

$$
\begin{equation*}
A_{w} d(n)=A_{w} d(n-r)+\left(A_{w}-B_{w}\right) r+k \tag{6.11}
\end{equation*}
$$

Since $A_{w}>0,(6.11)$ contradicts the fact that $D(x)$ cannot be continued. Put

$$
\begin{equation*}
E(x)=\sum_{n=1}^{\infty} x^{e(n)} \tag{6.12}
\end{equation*}
$$

Then, by Theorem 3.4,
(6.13)

$$
\mathrm{E}(\mathrm{x})=\frac{\mathrm{x}}{1-\mathrm{x}}+2 \mathrm{~A}(\mathrm{x})
$$

Also

$$
\begin{equation*}
(1-x)^{-1} A(x)=\sum_{n=1}^{\infty} e(n) x^{n} \tag{6.14}
\end{equation*}
$$

In the next place, by (3.8), (3.9), and (3.10),

$$
\begin{aligned}
\mathrm{A}(\mathrm{x}) & =\sum_{1}^{\infty} \mathrm{x}^{\mathrm{a}^{2}(\mathrm{n})}+\sum_{1}^{\infty} \mathrm{x}^{\mathrm{ab}(\mathrm{n})}+\sum_{1}^{\infty} \mathrm{x}^{\mathrm{ac}(\mathrm{n})} \\
& =\mathrm{x}^{-2} \mathrm{~B}(\mathrm{x})+\left(1+\mathrm{x}^{-1}\right) \mathrm{F}_{\mathrm{ab}}(\mathrm{x})
\end{aligned}
$$

Since

$$
\mathrm{A}(\mathrm{x})+\left(1+\mathrm{x}^{-1}\right) \mathrm{B}(\mathrm{x})=\frac{\mathrm{x}}{1-\mathrm{x}}
$$

it follows that

$$
\begin{equation*}
(1+x)^{2} \mathrm{~F}_{\mathrm{ab}}(\mathrm{x})=\left(1+\mathrm{x}+\mathrm{x}^{2}\right) \mathrm{A}(\mathrm{x})-\frac{\mathrm{x}}{1-\mathrm{x}} \tag{6.15}
\end{equation*}
$$

Let $w, w^{\prime}$ be two words of equal weight. Then by (5.21),

$$
\begin{equation*}
x^{C}{ }_{w} F_{w}(x)=x^{C} w^{\prime} F_{w^{\prime}}(x) \tag{6.16}
\end{equation*}
$$

Thus it suffices to consider the functions

We have

$$
F_{a^{k}}^{(x)} \quad(k=1,2,3, \cdots)
$$

By (5.8)

$$
\mathrm{F}_{\mathrm{a}^{\mathrm{k}}}(\mathrm{x})=\mathrm{F}_{\mathrm{a}^{\mathrm{k}-1}}(\mathrm{x})+\mathrm{F}_{\mathrm{a}^{k_{b}}}(\mathrm{x})+\mathrm{F}_{\mathrm{a}^{\mathrm{k}} \mathrm{c}}(\mathrm{x})
$$

$$
\begin{aligned}
a^{k} b(n) & =u_{k} a b(n)+2 u_{k-1} b(n)-\left(u_{k+1}-1\right) \\
& =u_{k}(3 a(n)+2 n)+2 u_{k-1}(a(n)+2 n)-\left(u_{k+1}-1\right) \\
& =\left(3 u_{k}+2 u_{k-1}\right) a(n)+2\left(u_{k}+2 u_{k-1}\right) n-\left(u_{k+1}-1\right) \\
& =u_{k+2} a(n)+2 u_{k+1} n-\left(u_{k+1}-1\right) \\
& =a^{k+2}(n)+2^{k+1}
\end{aligned}
$$

$$
\mathrm{a}^{\mathrm{k}} \mathrm{c}(\mathrm{n})=\mathrm{u}_{\mathrm{k}} \mathrm{ac}(\mathrm{n})+2 \mathrm{u}_{\mathrm{k}-1} \mathrm{c}(\mathrm{n})-\left(\mathrm{u}_{\mathrm{k}+1}-1\right)
$$

$$
=u_{k}(3 a(n)+2 n-1)+2 u_{k-1}(a(n)+2 n-1)-\left(u_{k+1}-1\right)
$$

$$
=u_{k+2} a(n)+2 u_{k+1} n-\left(2 u_{k+1}-1\right)
$$

[Continued on page 550.]

$$
=a^{k+2}(n)+u_{k+2}
$$
