DYING RABBIT PROBLEM REVIVED
BROTHER U. ALFRED, ST. MARY'S COLLEGE, CALIFORNIA

In the first issue of the Fibonacci Quarterly the following problem was proposed [1]. Suppose that in the original Fibonacci rabbit breeding problem, we allow for the dying of rabbits. Those that are bred in February, for example, begin to breed in April and continue breeding monthly through February of the following year. At the end of this month they die. What would be the formula for the number of pairs of rabbits at the end of n months for n ≥ 13?

Originally, it was thought that the rabbits removed would constitute a sequence which could be readily identified with an expression involving Fibonacci numbers. But after several attempts by a number of people it appeared that it would be difficult to arrive at an answer by straightforward intuition. The following development will indicate why this is so.

First of all we shall set down a table showing how the rabbits propagate over a two-year period. It will be noted that the original table values for the case in which rabbits do not die are positive while a negative term is introduced to show the effect of allowing rabbits to die.

For the sake of convenience, a table of the negative values is formed with a shift of numbering, the first row in the new table corresponding to \( n = 14 \) in the old.

\[
\begin{array}{cccccc}
 n & a_n & a_{n-1} & a_n & F_n & T_n \\
1 & 1   & 1      & 1   & 1 & 4 \\
2 & 3   & 1      & 3   & 1 & 8 \\
3 & 5   & 3      & 5   & 2 & 15 \\
4 & 10  & 5      & 10  & 3 & 28 \\
5 & 18  & 10     & 18  & 5 & 51 \\
6 & 33  & 18     & 33  & 8 & 92 \\
7 & 59  & 33     & 59  & 13 & 164 \\
8 & 105 & 59     & 105 & 21 & 290 \\
9 & 185 & 105    & 185 & 34 & 509 \\
10 & 324 & 185    & 324 & 55 & 888 \\
11 & 564 & 324    & 564 & 89 & 1541 \\
\end{array}
\]

The following relations may be noted apart from those implicit in the column headings.

\[
a_{n+1} = a_n + a_{n-1} + F_n \\
T_n = 2a_n + a_{n-1} + F_n
\]

Using the relation for \( a_{n+1} \) we obtain the following succession of relations.

\[
a_1 = 1 \\
a_2 = a_1 + a_0 + F_1 = 2 + F_1 \\
a_3 = a_2 + a_1 + F_2 = 3 + F_1 + F_2 \\
a_4 = a_3 + a_2 + F_3 = 5 + 2F_1 + F_2 + F_3 \\
a_5 = a_4 + a_3 + F_4 = 8 + 3F_1 + 2F_2 + F_3 + F_4 \\
a_6 = a_5 + a_4 + F_5 = 13 + 5F_1 + 3F_2 + 2F_3 + F_4 + F_5 \\
a_7 = a_6 + a_5 + F_6 = 21 + 8F_1 + 5F_2 + 3F_3 + 2F_4 + F_5 + F_6
\]

It is clear that a formula involving Fibonacci numbers is emerging. For example, \( a_7 \) can be written:
1963] DYING RABBIT PROBLEM REVIVED 55

\[ a_7 = F_8 + F_6 F_1 + F_5 F_2 + F_4 F_3 + F_3 F_4 + F_2 F_5 + F_1 F_6 \]

and in general, it could be shown by mathematical induction that:

\[ a_n = F_{n+1} + \sum_{k=1}^{n-1} F_k F_{n-k} \]

The problem then reduces to finding a formula for the summation on the right. Using the roots \( r \) and \( s \) of the equation \( x^2 - x - 1 = 0 \) in terms of which:

\[ F_n = \frac{r^n - s^n}{\sqrt{5}} \quad \text{and} \quad L_n = r^n + s^n \]

where

\[ r = \frac{1 + \sqrt{5}}{2} \quad \text{and} \quad s = \frac{1 - \sqrt{5}}{2} \]

we have

\[ F_k F_{n-k} = \left( \frac{r^k - s^k}{\sqrt{5}} \right) \left( \frac{r^{n-k} - s^{n-k}}{\sqrt{5}} \right) \]

\[ = \left( \frac{r^n + s^n}{\sqrt{5}} \right) - \frac{r^k s^k (r^{n-2k} + s^{n-2k})}{5} \]

But \( r^k s^k = (-1)^k \) since \( rs \), the product of the roots of the given equation, is the constant term \(-1\). Thus

\[ F_k F_{n-k} = \frac{L_n + (-1)^{k+1} L_{n-2k}}{5} \]

This is the expression that must be summed from 1 to \( n - 1 \) over \( k \). However, since the first part \( L_n/5 \) does not involve \( k \), it is essentially a constant taken \( n - 1 \) times so that this part of the sum becomes \((n - 1)L_n/5\). The second half is

\[ \frac{1}{5} \sum_{k=1}^{n-1} (-1)^{k+1} L_{n-2k} = \frac{1}{5} \left[ L_{n-2} - L_{n-4} + L_{n-6} - L_{n-8} + \ldots + (-1)^n L_{n-2(n-1)} \right] \]

\[ = \frac{1}{5} \left[ F_{n-1} + F_{n-3} - F_{n-3} - F_{n-5} + F_{n-5} + F_{n-7} - \ldots \right. \]

\[ \left. + (-1)^n F_{n+3} + (-1)^{n+1} F_{n+1} \right] \]
It will be noted that all terms cancel out except the first and last and since

\((-1)^n F_{-n+1} = F_{n-1}\),

the total of the summation is \(2F_{n-1}/5\). Thus the value of \(a_n\) is given by the expression

\[
a_n = F_{n+1} + \frac{(n-1)}{5} L_n + \frac{2F_{n-1}}{5}.
\]

Substituting \(L_n = F_{n+1} + F_{n-1}\), this can be transformed to

\[
a_n = \frac{1}{5} \left[ (n+4)F_{n+1} + (n+1)F_{n-1} \right]
\]

As a check, for \(n = 7\), this becomes

\[
\frac{1}{5} \left[ 11 \cdot 21 + 8 \cdot 8 \right] = 59
\]

After suitable transformations one can find a value of \(T_n\) equal to

\[
\frac{1}{5} \left[ (3n + 10)F_{n+1} + (n + 6)F_n \right]
\]

Reconverting back to our original notation, the solution of the dying rabbit problem can be expressed as follows \((n \geq 13)\):

\[
F_{n+1} - \frac{1}{5} \left[ (3n - 29)F_{n+1} - (n - 7)F_{n-13} \right]
\]
