## FIBONACCI PRIMITIVE ROOTS

Computation and Mathematics Dept., Naval Ship R \& D Center, Washington, D. C.

## 1. INTRODUCTION

A prime p possesses a Fibonacci Primitive Root g if g is a primitive root of $p$ and if it satisfies

$$
\begin{equation*}
\mathrm{g}^{2}=\mathrm{g}+1 \quad(\bmod \mathrm{p}) \tag{1}
\end{equation*}
$$

It is obvious that if (1) holds then so do
(2)

$$
\mathrm{g}^{3}=\mathrm{g}^{2}+\mathrm{g} \quad(\bmod \mathrm{p})
$$

$$
\mathrm{g}^{4}=\mathrm{g}^{3}+\mathrm{g}^{2} \quad(\bmod \mathrm{p})
$$

etc.
For example, $g=8$ is one of the four primitive roots of $p=11$ (the others being $2,6,7$ ), and $g=8$ (only) satisfies (1). Thus, its powers $8^{\text {n }}$ $(\bmod 11)$ are

$$
1,8,9,6,4,10, \cdots \quad(\bmod 11)
$$

and may be computed not only by

$$
9=8^{2}, \quad 6=9 \cdot 8, \quad 4=9 \cdot 8, \cdots \quad(\bmod 11)
$$

but also, more simply, by

$$
9=8+1, \quad 6=9+8, \quad 4=6+9, \cdots \quad(\bmod 11)
$$

Thus the name: Fibonacci Primitive Root.
The brief Table 1 shows every $p<200$ that has an F. P. R., and every such g satisfying $0<\mathrm{g}<\mathrm{p}$ that it possesses. By incomplete induction (a

## TABLE 1

| $\underline{p}$ | g | p | g |
| :---: | :---: | :---: | :---: |
| 5 | 3 | 71 | 63 |
| 11 | 8 | 79 | 30 |
| 19 | 15 | 109 | 11, 99 |
| 31 | 13 | 131 | 120 |
| 41 | 7, 35 | 149 | 41, 109 |
| 59 | 34 | 179 | 105 |
| 61 | 18, 44 | 191 | 89 |

fine old expression seldom used these days), we observe the following properties, all of which are easily proved in the next section.
A. Except for the singular $p=5$, all $p$ having an F.P.R. are $= \pm 1$ $(\bmod 10)$.
B. But not all $p= \pm 1(\bmod 10)$ have an F.P.R., since, e. g., $p=29$ and 101 do not.
C. Except for the singular $p=5$, the number of $g$ in $0<g<p$, if any, is 1 or 2 according as $p \equiv-1$ or $+1(\bmod 4)$.
D. In the latter case, the two g satisfy

$$
\begin{equation*}
g_{1}+g_{2}=p+1 \tag{4}
\end{equation*}
$$

## 2. ELEIMENTARY PROPERTIES

The solutions of (1) are

$$
\begin{equation*}
g=(1 \pm \sqrt{5}) 2^{-1} \quad(\bmod p) \tag{5}
\end{equation*}
$$

and therefore exist if, and only if, $p=5, \mathrm{~g}=3$, or $\mathrm{p}=10 \mathrm{k} \pm 1$, since only these $p$ have 5 as a quadratic residue. This proves A. For $p=29$, the two solutions of (1) are $g=6$ and 24 , but since these are also quadratic residues of 29 , they cannot be primitive roots, thus proving $B$. The product of the two solutions (5) is given by
(6)

$$
g_{1} g_{2} \equiv-1 \quad(\bmod p)
$$

Thus, if $p \equiv-1(\bmod 4)$, one $g$ is a quadratic residue and one $g$ is not. There can, therefore, then be at most one F.P.R. On the other hand, for $\mathrm{p} \equiv+1(\bmod 4)$, consider

$$
\mathrm{g}_{2} \equiv-\mathrm{g}_{1}^{-1}
$$

If $\mathrm{g}_{1}$ is primitive, and $\mathrm{g}_{2}$ is of order m , then

$$
\mathrm{g}_{1}^{\mathrm{m}} \equiv(-1)^{\mathrm{m}}
$$

Therefore, $m$ is even, and so $g_{2}$ is primitive also. Thus, $g_{1}$ and $g_{2}$ are both primitive, or neither is. This completes C. Finally,

$$
\begin{equation*}
\mathrm{g}_{1}+\mathrm{g}_{2} \equiv 1 \quad(\bmod \mathrm{p}) \tag{7}
\end{equation*}
$$

and (4) follows from $0<\mathrm{g}<\mathrm{p}$.

## 3. THE ASYMPTOTIC DENSITY

Let $F(x)$ be the number of primes $p \leq x$ having an F.P.R. (We do not distinguish in this count whether p has one ortwo.) Then with $\pi(\mathrm{x})$ being the total number of primes $\leq x$, we

$$
\text { Conjecture: As } x \rightarrow \infty \text {, }
$$

$$
\begin{equation*}
\frac{\mathrm{F}(\mathrm{x})}{(\mathrm{x})} \sim \frac{27 \mathrm{~A}}{38}=0.2657054465 \cdots \tag{8}
\end{equation*}
$$

where

$$
\begin{equation*}
A=\prod_{p=2}^{\infty}\left(1-\frac{1}{p(p-1)}\right)=0.3739558136 \cdots \tag{9}
\end{equation*}
$$

is Artin's constant.

Artin originally conjectured, cf. [1], [2, page 81] that if $\nu_{\mathrm{a}}(\mathrm{x})$ is the number of $\mathrm{p} \leq \mathrm{x}$ having a as a primitive root, and if

$$
a \neq b^{n} \quad(n>1)
$$

then

$$
\begin{equation*}
\frac{\nu_{\mathrm{a}}(\mathrm{x})}{\pi(\mathrm{x})} \sim \mathrm{A} . \tag{10}
\end{equation*}
$$

Subsequently, [3] it was found that the heuristic argument was faulty for $\mathrm{a}=$ $5,-3$, and infinitely many other a but it was still considered reasonable for $a=2,3,6,7,10$, etc. Both heuristically and empirically, Eq. (10) seems correct for these $a$, and Hooley [4] recently proved that (10) is then true provided one assumes a sufficient number of Riemann Hypotheses.

The heuristic argument for (8) is similar to that which leads to (10), but we must modify two of the factors in (9). Consider the primes in the eight residue classes

$$
20 \mathrm{k}+1,3,7,9,11,13,17,19
$$

Those in $20 \mathrm{k}+3,7,13,17$ cannot have an F. P. R. For those in $20 \mathrm{k}+11$, 19 the factor

$$
1-\frac{1}{2(2-1)}
$$

in (9) must be deleted. This represented the probability that a is not a quadratic residue and therefore could be a primitive root. But for $20 \mathrm{k}+11,19$, one of $g_{1}$ and $g_{2}$ must always be a quadratic nonresidue as we have shown with (6). The factor

$$
1-\frac{1}{5(5-1)}
$$

in (9) represented the probability that a is not a quintic residue and therefore could be a primitive root. For $20 \mathrm{k}+9,19 \mathrm{p}$ has no quintic residues since these p are not $\equiv 1(\bmod 5)$, and so this factor is deleted. For $20 \mathrm{k}+1$, 11, $p$ is always $\equiv 1(\bmod 5)$, and the factor must be changed to

$$
1-\frac{1}{5}
$$

Therefore, the expected density of $p$ in these eight residue classes having an F. P. R. is the following:

| $20 \mathrm{k}+1$ | $16 \mathrm{~A} / 19$ | $20 \mathrm{k}+11$ | $32 \mathrm{~A} / 19$ |
| :---: | :---: | :---: | :---: |
| $20 \mathrm{k}+3$ | 0 | $20 \mathrm{k}+13$ | 0 |
| $20 \mathrm{k}+7$ | 0 | $20 \mathrm{k}+17$ | 0 |
| $20 \mathrm{k}+9$ | $20 \mathrm{~A} / 19$ | $20 \mathrm{k}+19$ | $40 \mathrm{~A} / 19$ |

As $x \rightarrow \infty$, the eight classes of primes are equinumerous, and so (8) follows from this table by averaging these densities. On the other hand, it is known that the number of primes in

$$
20 \mathrm{k}+1, \quad 20 \mathrm{k}+9
$$

will generally lag somewhat behind the other six classes since 1 and 9 are quadratic residues of $20, \mathrm{cf}$. [5]. We therefore expect that the convergence of $\mathrm{F}(\mathrm{x}) / \pi(\mathrm{x})$ to $27 \mathrm{~A} / 38$ will be mostly from above.

The empirical facts are given in Table 2.

TABLE 2

| $x$ | $\underline{F}(\mathrm{x})$ | (x) | $\underline{F}(\mathrm{x}) / \mathrm{m}(\mathrm{x})$ |
| :---: | :---: | :---: | :---: |
| 500 | 31 | 95 | 0.3263 |
| 1000 | 46 | 168 | 0.2738 |
| 1500 | 66 | 239 | 0.2762 |
| 2000 | 81 | 303 | 0.2673 |
| 2500 | 97 | 367 | 0.2643 |

This seems thoroughly satisfactory.
It seems likely that one could transcribe Hooley's theory [4] to the present variant, and thereby prove (8), assuming a sufficient number of Riemann Hypotheses. But the theory in [4] is by no means simple, and this transcription has not been attempted so far.

## 4. SEVERAL REFERENCES

In closing, we indicate three references related to the concept developed here. The idea for a Fibonacci Primitive Root was suggested by Exercise 158 in [2, page 206]. It is shown there that if g is any primitive root of any prime $p$, the sequence of first differences

$$
\begin{equation*}
g^{\mathrm{n}+1}-\mathrm{g}^{\mathrm{n}} \quad(\bmod \mathrm{p}) \tag{11}
\end{equation*}
$$

is the same as the sequence

$$
\begin{equation*}
\mathrm{g}^{\mathrm{n}-\mathrm{d}} \quad(\bmod \mathrm{p}) \tag{12}
\end{equation*}
$$

for some fixed displacement $d$. If, now, one has the first $d$ powers of $g$ :

$$
1, \mathrm{~g}, \mathrm{~g}^{2}, \cdots, \mathrm{~g}^{\mathrm{d}}
$$

one can obtain all further powers additively from (11). Our construction here forces $d=1$ and therefore allows this additive computation ab initio.

In [6], W. Schooling gives a curious method of computing logarithms based on the fact that all powers of

$$
\varphi=(1+\sqrt{5}) / 2
$$

can be computed additively:

$$
\begin{aligned}
& \varphi^{2}=\varphi+1 \\
& \varphi^{3}=\varphi^{2}+\varphi,
\end{aligned}
$$
