# CONCERNING LATTICE PATHS AND FIBONACCI NUMBERS 

DOUGLAS R. STOCKS, JR.
Arlington State College, Arlington, Texas
R. E. Greenwood [l] has investigated plane lattice paths from $(0,0)$ to ( $n, n$ ) and has found a relationship between the number of paths in a certain restricted subclass of such paths and the Fibonacci sequence. Considering such paths and using a method of enumeration different from that used by Greenwood, an unusual representation of Fibonacci's sequence is suggested.

The paths considered hereare comprised of steps of three types: (i) horizontal from ( $x, y$ ) to ( $x+1, y$ ); (ii) vertical from ( $x, y$ ) to ( $x, y+1$ ); and (iii) diagonal from ( $\mathrm{x}, \mathrm{y}$ ) to ( $\mathrm{x}+\mathrm{l}, \mathrm{y}+1$ ).

$$
\begin{aligned}
& \text { - } \mathrm{V}_{5} \\
& \text { - } \mathrm{V}_{4} \\
& \text { - } \mathrm{V}_{3} \\
& \text { - } \mathrm{V}_{2} \\
& \text { - } \mathrm{V}_{1} \\
& \begin{array}{lllll}
\mathrm{H}_{5} & \mathrm{H}_{4} & \mathrm{H}_{3} & \mathrm{H}_{2} & \mathrm{H}_{1}
\end{array}
\end{aligned}
$$

Figure 1

In the interest of simplicity of representation, we will here consider the paths from $H_{i}$ to $V_{i}$, for each positive integer i. Note that the number of paths from $H_{i}$ to $V_{i}$ is the number of paths from $(0,0)$ to (i, i). However, instead of considering the total number of paths from $H_{i}$ to $V_{i}$ as was done by Greenwood, we will count only the number of paths from $H_{i}$ to $V_{i}$ which do not contain as subpaths any of the paths from $H_{j}$ to $V_{j}$, for j < i . This number plus the number of paths from $H_{i-1}$ to $\mathrm{V}_{\mathrm{i}-1}$ is the total number of paths from $H_{i}$ to $V_{i}$. The use of this counting device suggest the

Theorem:
Let

$$
\begin{aligned}
1_{D} & =1 \\
2_{D} & =\left[\frac{D-1}{2}\right], \text { where }[] \text { denotes the greatest integer functior } \\
3_{D} & =3_{D-1}+2_{D-1} \\
4_{D} & =4_{D-2}+3_{D-2} \\
& \cdots \\
(2 n)_{D} & =(2 n)_{D-2}+(2 n-1)_{D-2} \\
(2 n+1)_{D} & =(2 n+1)_{D-1}+(2 n)_{D-1} \\
& \cdots
\end{aligned}
$$

with the restriction that $k_{D}=0$ if $k>D$. For each positive integer D, let

D

$$
f(D)=\sum_{k=1} k_{D}
$$

The sequence $\{f(D) \mid D=1,2,3, \ldots\}$ is the Fibonacci sequence.
The proof is direct and is therefore omitted.
The geometric interpretation of the numbers $k_{D}$ and $f(D)$ mentioned in the theorem is interesting. However, before considering this interpretation it is necessary to define a section of a path. For this purpose we will now consider a path as the point set to which $p$ belongs if and only if for some step ( $(x, y),(u, v)$ ) of the path, $p$ belongs to the line interval whose end points are ( $x, y$ ) and ( $u, v$ ). A section of a path is a line interval which is a subset of the path and which is not a subset of any other line interval each of whose points is a point of the path.

The above mentioned geometric interpretation follows: By definition $f(1)=1$. For each positive integer $D \geq 2$, let $L_{D}$ denote the set of paths from $H_{D}$ to $V_{D}$ which do not contain as subpaths any of the pathsfrom $H_{j}$ to $V_{j}$, for $j<D$. $f(D)$ is the number of paths belonging to the set $L_{D^{\circ}} k_{D}$ is the number of paths in the subset $X$ of $L_{D}$ such that $x$ belongs to $X$ if and only if $x$ contains as subsets exactly $k$ diagonal sections.

Figure 2 portrays the five paths which belong to $L_{5}$. In Figure 2a appears the one path of $L_{5}$ which contains only one diagonal section $\left(l_{5}=1\right)$. The two paths of $L_{5}$ which contain exactly two diagonal sections appear in Figure $2 \mathrm{~b}\left(2_{5}=2\right)$. In Figure 2 c the two paths of $L_{5}$ which contain exactly three diagonal sections are shown ( $3_{5}=2$ ). It is noted that $4_{5}=5_{5}=0$.

Fig. 2a
$l_{5}=1$

Fig. 2b
$2_{5}=2$

Fig. 2c
$3_{5}=2$

$$
f(5)=1+2+2+0+0=5
$$
