# RESIDUES OF FIBONACCI-LIKE SEQUENCES 

LAURENCE TAYLOR
Oak Ridge, Tennessee

In the February, 1964, issue of the Fibonacci Quarterly, Brother U. Alfred [1] advanced the conjecture (later proved by J. H. Halton [2]) that, when any Fibonacci number is divided by another Fibonacci number, one or the other of the least positive and negative residues is again a Fibonacci number. The object of this paper is to prove that the only Fibonacci-like sequence for which this is true is the Fibonacci sequence. If zero is excluded as a remainder, then the Lucas sequence has the above property.

The proof falls naturally into two parts. The first part will be to show that every Fibonacci-like sequence, modulo any member of the sequence, is congruent to a sequence made up of a subsequence of the original sequence and the negatives of these values. The second part will be to show that these subsequences are actually remainders of the divisor for only the Fibonacci and Lucas sequences.

Obviously, a sequence has the property described above if and only if any non-zero integral multiple of it does. Since any divisor of two neighboring members of Fibonacci-like sequences divides every member of the sequence, we will consider only sequences with neighboring termis relatively prime. In what follows, $H_{i}$ will denote the $i^{\text {th }}$ member of a general Fibonacci-like sequence defined by $H_{i+1}=H_{i}+H_{i-1}$, where $H_{0}$ and $H_{1}$ are arbitrary. The set of integers will be denoted by $I$, the set of non-negative integers by $P$, and the set of natural numbers by N .

## PART I

Since it is easily established by induction that

$$
\mathrm{H}_{\mathrm{m}+\mathrm{k}}=\mathrm{F}_{\mathrm{k}} \mathrm{H}_{\mathrm{m}-1}+\mathrm{F}_{\mathrm{k}+1} \mathrm{H}_{\mathrm{m}},
$$

for all integers m and k , the following two lemmas readily follow.
Lemma 1: $H_{m+i} \equiv F_{i} H_{m-1}\left(\bmod H_{m}\right)$ for all integers $i$.
Lemma 2: $H_{m-i} \equiv \mathrm{~F}_{-\mathrm{i}} \mathrm{H}_{\mathrm{m}-1} \equiv(-1)^{\mathrm{i}+1} \mathrm{H}_{\mathrm{m}+\mathrm{i}}\left(\bmod \mathrm{H}_{\mathrm{m}}\right)$ for all integersi.

It is known that any number must eventually divide one of the Fibonacci numbers, and that $F_{n-1}^{2}=F_{n-2} F_{n}+(-1)^{n}$ for all integers $n$. Applying these results and Lemma 1, it is not difficult to prove Lemmas 3 and 4.

Lemma 3: Let n be any integer such that $\mathrm{F}_{\mathrm{n}} \equiv 0\left(\bmod \mathrm{H}_{\mathrm{m}}\right)$. Then

$$
\mathrm{H}_{\mathrm{m} \pm \mathrm{n}} \equiv 0\left(\bmod \mathrm{H}_{\mathrm{m}}\right)
$$

Lemma 4: For the $n$ of Lemma 3, $F_{n-1}^{2} \equiv(-1)^{n}\left(\bmod H_{m}\right)$. Lemma 5: For the n of Lemma 3, and for all integers i ,

$$
\mathrm{F}_{\mathrm{n}-1} \mathrm{H}_{\mathrm{m}-\mathrm{i}} \equiv(-1)^{\mathrm{n}+\mathrm{i}+1} \mathrm{H}_{\mathrm{m}-\mathrm{n}+\mathrm{i}}\left(\bmod \mathrm{H}_{\mathrm{m}}\right)
$$

Proof: The proof is by induction on $i$. For $i=0$, apply Lemma 3. For $\mathrm{i}=1$, apply Lemma 1. Assume that Lemma 5 holds for $\mathrm{i}=\mathrm{k}-1$ and $\mathrm{i}=\mathrm{k}-2$, or that

$$
\begin{aligned}
& \left.\mathrm{F}_{\mathrm{n}-1} \mathrm{H}_{\mathrm{m}-(\mathrm{k}-1)} \equiv(-1)^{\mathrm{n}+\mathrm{k}_{\mathrm{H}}^{\mathrm{m}-\mathrm{n}+(\mathrm{k}-1)}} \text { (mod} \mathrm{H}_{\mathrm{m}}\right) \\
& \mathrm{F}_{\mathrm{n}-1} \mathrm{H}_{\mathrm{m}-(\mathrm{k}-2)} \equiv(-1)^{\mathrm{n}+\mathrm{k}-1} \mathrm{H}_{\mathrm{m}-\mathrm{n}+\left(\mathrm{k}-\frac{2}{2}\right)}\left(\bmod \mathrm{H}_{\mathrm{m}}\right)
\end{aligned}
$$

Subtracting the first formula from the second yields the expected result for i $=\mathrm{k}$. Hence, the formula is correct for all $\mathrm{i} \in \mathrm{P}$. Lemma 2 can be used to extend the result to include negative integers.

Lemma 6: Let $t=n q+r$. Then, if $q \in N$ and $F_{n} \equiv 0\left(\bmod H_{m}\right)$,

$$
\mathrm{H}_{\mathrm{m}-\mathrm{n}+\mathrm{t}} \equiv \mathrm{~F}_{\mathrm{r}} \mathrm{~F}_{\mathrm{n}-1}^{\mathrm{q}-1} \mathrm{H}_{\mathrm{m}-1}\left(\bmod \mathrm{H}_{\mathrm{m}}\right)
$$

Proof: The proof is once again by induction on $q$. When $q=1$, the expression above becomes identical to Lemma 1. Assume that Lemima 6 holds for $q=k-1$, or that

$$
\mathrm{H}_{\mathrm{m}-\mathrm{n}+\mathrm{t}} \equiv \mathrm{~F}_{\mathrm{t}-(\mathrm{k}-1) \mathrm{n}} \mathrm{~F}_{\mathrm{n}-1}^{\mathrm{k}-2} \mathrm{H}_{\mathrm{m}-1}\left(\bmod \mathrm{H}_{\mathrm{m}}\right)
$$

But, $\quad \mathrm{F}_{\mathrm{t}-(\mathrm{k}-1) \mathrm{n}}=\mathrm{F}_{\mathrm{t}-\mathrm{kn}} \mathrm{F}_{\mathrm{n}-1}+\mathrm{F}_{\mathrm{t}-\mathrm{kn}+1} \mathrm{~F}_{\mathrm{n}} \equiv \mathrm{F}_{\mathrm{t}-\mathrm{kn}} \mathrm{F}_{\mathrm{n}-1}\left(\bmod \mathrm{H}_{\mathrm{m}}\right)$, since $\mathrm{H}_{\mathrm{m}}$ divides $\mathrm{F}_{\mathrm{n}}$ by hypothesis. Substituting back into the formula above,

$$
\mathrm{H}_{\mathrm{m}-\mathrm{n}+\mathrm{t}} \equiv \mathrm{~F}_{\mathrm{t}-\mathrm{kn}} \mathrm{~F}_{\mathrm{n}-1}^{\mathrm{k}-1} \mathrm{H}_{\mathrm{m}-1}\left(\bmod \mathrm{H}_{\mathrm{m}}\right)
$$

Hence, Lemma 6 is true for all $q \in N$.
Theorem 1: For every $i \in I$, there exists a $k \in I, m-n \leqslant k \leqslant m$, such that

$$
\mathrm{H}_{\mathrm{i}} \equiv \pm \mathrm{H}_{\mathrm{k}}\left(\bmod \mathrm{H}_{\mathrm{m}}\right)
$$

where $n$ is the smallest natural number such that $\mathrm{F}_{\mathrm{n}} \equiv 0\left(\bmod \mathrm{H}_{\mathrm{m}}\right)$.
Proof: Let $\mathrm{i}=\mathrm{m}-\mathrm{n}+\mathrm{t}, \mathrm{k}=\mathrm{m}-\mathrm{n}+\mathrm{r}$, and $\mathrm{t}=\mathrm{nq}+\mathrm{r}, \quad 0 \leq \mathrm{r} \leq \mathrm{n}$. The case $q=0$ is trivial, since then $t=p$ and $i=k$. The case $q<0$ is equivalent to $t<0$. But, by Lemma 2 and properties of congruences,

$$
\mathrm{H}_{\mathrm{m}-\mathrm{n}+\mathrm{t}} \equiv(-1)^{\mathrm{t}+\mathrm{t}^{2}} \mathrm{H}_{\mathrm{m}-\mathrm{n}+(-\mathrm{t})}\left(\bmod \mathrm{H}_{\mathrm{m}-\mathrm{n}}\right) \equiv(-1)^{\mathrm{t}+\mathrm{H}_{\mathrm{m}-\mathrm{n}+(-\mathrm{t})}\left(\bmod \mathrm{H}_{\mathrm{m}}\right) . . . . .}
$$

Since $-\mathrm{t}>0$, we need consider only the case $\mathrm{t}>0$ or $q \in N$. By Lemma 6,

$$
\mathrm{H}_{\mathrm{m}-\mathrm{n}+\mathrm{t}} \equiv \mathrm{~F}_{\mathrm{r}} \mathrm{~F}_{\mathrm{n}-1}^{\mathrm{q}-1} \mathrm{H}_{\mathrm{m}-1}\left(\bmod \mathrm{H}_{\mathrm{m}}\right)
$$

By Lemma 1,

$$
\mathrm{F}_{\mathrm{r}} \mathrm{H}_{\mathrm{m}-1} \equiv(-1)^{\mathrm{r}+1} \mathrm{H}_{\mathrm{m}-\mathrm{r}}\left(\bmod \mathrm{H}_{\mathrm{m}}\right)
$$

Substituting,

$$
\mathrm{H}_{\mathrm{m}-\mathrm{n}+\mathrm{t}} \equiv(-1)^{\mathrm{r}+1} \mathrm{~F}_{\mathrm{n}-1}^{\mathrm{q}-1} \mathrm{H}_{\mathrm{m}-\mathrm{r}}\left(\bmod \mathrm{H}_{\mathrm{m}}\right)
$$

By Lemma 4,

$$
\mathrm{F}_{\mathrm{n}-1}^{2} \equiv(-1)^{\mathrm{n}} \quad\left(\bmod \mathrm{H}_{\mathrm{m}}\right)
$$

We must now distinguish two cases.

Case I: If $q$ is odd,

$$
\mathrm{F}_{\mathrm{n}-1}^{\mathrm{q}-1}=(-1)^{\mathrm{n}(\mathrm{q}-1) / 2}\left(\bmod \mathrm{H}_{\mathrm{m}}\right),
$$

leading to $H_{m-n+t}= \pm H_{m-r}\left(\bmod H_{m}\right)$, where $m-n \leq m-r \leq m$.
Case 2: If $q$ is even,

$$
\mathrm{F}_{\mathrm{n}-1}^{\mathrm{q}-1}=(-1)^{\mathrm{n}(\mathrm{q}-2) / 2} \mathrm{~F}_{\mathrm{n}-1}\left(\bmod \mathrm{H}_{\mathrm{m}}\right)
$$

By Lemma 5,

$$
\mathrm{F}_{\mathrm{n}-1} \mathrm{H}_{\mathrm{m}-\mathrm{r}} \equiv(-1)^{\mathrm{n}+\mathrm{r}+1} \mathrm{H}_{\mathrm{m}-\mathrm{n}+\mathrm{r}}\left(\bmod \mathrm{H}_{\mathrm{m}}\right)
$$

Substituting these two results leads to

$$
\mathrm{H}_{\mathrm{m}-\mathrm{n}+\mathrm{t}} \equiv(-1)^{\mathrm{nq} / 2} \mathrm{H}_{\mathrm{m}-\mathrm{n}+\mathrm{r}}\left(\bmod \mathrm{H}_{\mathrm{m}}\right)
$$

where $0 \leqslant r \leqslant n$, so $m-n \leqslant m-n+r \leqslant m$.
In Theorem 1, if $H_{m}$ divides $H_{i}$, we can take $k=m$ or $k=m-n$. While every $H_{i}$ divides some other member of the sequence (see Lemma 3), it is necessary to notice that zero cannot appear as a member of the subsequence of Theorem 1 unless our Fibonacci-like sequence is the Fibonacci sequence itself. Since zero can occur as a remainder in any Fibonacci-like sequence and since Theorem 1, applied to Fibonacci numbers, leads to the theorem proved by Halton in [2], the only Fibonacci-like sequence which strictly fulfills the requirements of Brother Alfred's conjecture is the Fibonacci sequence.

In Part II, we will investigate Fibonacci-like sequences to determine if any other sequence leaves residues which, in all cases, are either zero or equal in absolute value to members of the original sequence.

## PART II

Now, if our sequence is to have the desired property, there must be a set of elements of the sequence whose absolute values are less than that of $\mathrm{H}_{\mathrm{m}}$. The first observation to be made about Fibonacci-like sequences is that
far to the right and to the left, the absolute values increase without limit. Hence, we need only examine a small section of the whole sequence to determine if it has the desired property.

There must be at least one $H_{i}$ with a minimal absolute value, and, because of the divergence of the sequence in both directions, there can be only a finite number of such minima.

Lemma 7: If $H_{0}$ is a minimum, $\left|H_{0}\right| \geq 2$, then, if $H_{1}>0$, the only possible remainder equal in absolute value to a member of the original sequence upon division by $H_{-2}$ is $\pm H_{0}$, and if $H_{1}<0$, the only such remainder for $H_{2}$ is $\pm \mathrm{H}_{0}$.

Proof: If $\mathrm{H}_{0}$ is negative, we will obtain the negative of the sequence for $\mathrm{H}_{0}$ positive. Hence, consider only $\mathrm{H}_{0} \geq 2$. None of $\mathrm{H}_{1}, \mathrm{H}_{2}, \mathrm{H}_{-1}, \mathrm{H}_{-2}$ can be a minima, since each of $\left|H_{i}\right|=H_{0} \geq 2, i= \pm 1, \pm 2$, leads to a contradiction.

If $H_{1}>0$, to avoid $\left|H_{j}\right|<H_{0}$ for some $i$, for the terms near $H_{0}$ we can have only the following:

$$
\begin{aligned}
\mathrm{H}_{-3}= & 3 \mathrm{H}_{0}+2 \alpha=\mathrm{H}_{1}+\alpha \\
\mathrm{H}_{-2}= & -\left(\mathrm{H}_{0}+\alpha\right) \\
\mathrm{H}_{-1}= & 2 \mathrm{H}_{0}+\alpha \\
\mathrm{H}_{0}= & \mathrm{H}_{0} \\
\mathrm{H}_{1}= & 3 \mathrm{H}_{0}+\alpha \\
\mathrm{H}_{2}= & 4 \mathrm{H}_{0}+\alpha \\
& \cdots \\
\mathrm{H}_{\mathrm{i}}= & \mathrm{L}_{\mathrm{i}+1} \mathrm{H}_{0}+\mathrm{F}_{\mathrm{i}} \alpha, \quad \alpha \geq 1,
\end{aligned}
$$

where $L_{n}$ and $F_{n}$ are respectively the $n^{\text {th }}$ Lucas and Fibonacci numbers.
If $\mathrm{H}_{1}<0$, with the conditions above we obtain

$$
\mathrm{H}_{\mathrm{i}}=(-1)^{\mathrm{i}}\left(\mathrm{~L}_{\mathrm{i}+1} \mathrm{H}_{0}+\mathrm{F}_{\mathrm{i}} \alpha\right)
$$

or a new sequence which, except for changes in sign, is the sequence for $H_{1}>$ 0 reflected about $H_{0}$. In particular, $H_{2}=-\left(H_{0}+\alpha\right)$.

Notice that the sequence diverges for $|i|>2$. From the sequence above, it is easy to see that the only remainder in the sequence for $H_{-2}$ will be $\pm \mathrm{H}_{0}$ when $H_{1}>0$, and when $H_{1}<0$, the only remainder for $H_{2}$ will be $\pm H_{0}$.

Lemma 8: If $\mathrm{H}_{0}$ is a minimum, $\left|\mathrm{H}_{0}\right| \geqslant 1$, and neither $\mathrm{H}_{2}$ nor $\mathrm{H}_{-2}$ is a minimum, then the only remainder equal in absolute valueto a member of the original sequence upon division by $\mathrm{H}_{-2}$ is $\pm \mathrm{H}_{0}$ when $\mathrm{H}_{1}>0$, and the only such remainder for $H_{2}$ is $\pm H_{0}$ when $H_{1}<0$.

Proof: Avoiding $\left|\mathrm{H}_{2}\right|=\left|\mathrm{H}_{0}\right|$ and $\left|\mathrm{H}_{-2}\right|=\left|\mathrm{H}_{0}\right|$ as well as $\left|\mathrm{H}_{\mathrm{i}}\right|<\left|\mathrm{H}_{0}\right|$ leads to the formulae of Lemma 7.

Lemma 9: If $\mathrm{H}_{0}$ is a minimum, $\left|\mathrm{H}_{0}\right| \geqslant 2$, then there exist numbers $H_{i}$ which leave remainders which are neither zero nor equal in absolute value to a member of the original sequence.

Proof: If any number $H_{j}$ is divided by $H_{0}$, the remainder must be less in absolute value than $H_{0}$, the minimum of the sequence. Thus, if $\left|H_{0}\right| \geqslant 2$, all remainders cannot be zero because any two adjacent terms are relatively prime, and any non-zero remainder is a number not equal in absolute value to a member of the original sequence. So $H_{0}$ is a number $H_{i}$ for the lemma.

Suppose we exclude division by $H_{0}$. Since $\left(H_{0}, H_{1}\right)=1$, $H_{1}$ is nota minimum. Either $H_{1}$ is positive or $H_{1}$ is negative. Without loss of generality (see proof of Lemma 7), we assume that $H_{1}$ is negative. By Theorem 1, if $\mathrm{n}_{2}$ is the least natural number such that $\mathrm{F}_{\mathrm{n}_{2}} \equiv 0\left(\bmod \mathrm{H}_{2}\right)$, and if $\mathrm{t}=\mathrm{qn}_{2}+$ $\mathrm{r}, 0 \leq \mathrm{r}<\mathrm{n}_{2}$, for q an odd number,

$$
\mathrm{H}_{2-\mathrm{n}_{2}+\mathrm{t}} \equiv \pm \mathrm{H}_{2-\mathrm{r}} \quad\left(\bmod \mathrm{H}_{2}\right)
$$

Now, $H_{2-r}=H_{0}$ if and only if $r=2$. If $\left|H_{0}\right| \geq 2,\left|H_{2}\right| \geq 3=F_{4}$, so $n_{2} \geq$ 4 , and at least $0 \leqslant r<4$. Set $t=\mathrm{qn}_{2}+3$ for an odd number q , say $\mathrm{q}=$ 1. Substituting, we have $\mathrm{H}_{5} \equiv \pm \mathrm{H}_{-1}\left(\bmod \mathrm{H}_{2}\right)$, and $\pm \mathrm{H}_{-1} \not \equiv \pm \mathrm{H}_{0}\left(\bmod \mathrm{H}_{2}\right)$ by inspecting the proof of Lemma 7. Thus, we can take $i=2$.

Lemma 10: If $\left|H_{0}\right|=1$ is a minimum, and neither $H_{2}$ nor $H_{-2}$ is a minimum, then there exist numbers $H_{i}$ which leave remainders which are neither zero nor equal in absolute value to a number in the original sequence.

Proof: Without loss of generality, we assume that $H_{1}<0$. If $\left|H_{2}\right| \geq 3$, so that $n_{2} \geq 4$, by Lemma 8 we can use the same proof as for Lemma 9. Since $\mathrm{H}_{2}$ is not a minimum, $\mathrm{H}_{2} \neq 1$ and $\mathrm{H}_{2} \neq-1$. The only remaining case is when $\left|\mathrm{H}_{2}\right|=2$, which leads only to the following sequence,
$\cdots,-23,14,-9,5,-4,1,-3,-2,-5,-7,-12,-19,-31,-50, \cdots$,
where $31 \equiv 8(\bmod -23)$ while neither $\pm 8$ nor $\pm 15$ is in the original sequence.
Theorem 2: The only sequences which possess the property that, upon division by a (non-zero) member of that sequence, the members of the sequence leave least positive or negative residues which are either zero or equal in absolute value to a member of the original sequence are the Fibonacci and Lucas sequences.

Proof: By Lemmas 9 and 10, for a sequence to possess the above property, its minimum must be either $\mathrm{H}_{0}=0$ or $\left|\mathrm{H}_{0}\right|=1$ with one of $\mathrm{H}_{2}$ and $\mathrm{H}_{-2}$ also a minimum.

If $H_{0}=0$, we can have only the Fibonacci sequence.
Considering the cases $\left|H_{0}\right|=1$ and $\left|H_{2}\right|=1 ;\left|H_{0}\right|=1$ and $\left|H_{-2}\right|=1$, leads to the Lucas sequence and the negative of the Lucas sequence.

It can be shown that, since when Theorem is applied to Lucas numbers, for each $L_{k},\left|L_{k}\right|<\left|L_{m}\right|$ or $L_{k}=0\left(\bmod L_{m}\right)$, that the Lucas numbers do indeed have the property of Theorem 2. The Fibonacci numbers are known to also have this property, as proved by Halton in [2].

Wehave used a minimum value greater than 2 as a criterion to determine if there exist numbers $H_{i}$ which leave remainders which do not satisfy Theorem 2. Another criterion is that such numbers $H_{i}$ exist if and only if $\left|H_{j}\right| \neq$ $\left|\mathrm{H}_{-j}\right|$ for any $j$, where the sequence has been renumbered so that either $H_{0}$ is the minimum or $\mathrm{H}_{0}$ is between the two minima $\mathrm{H}_{1}$ and $\mathrm{H}_{-1}$. This second criterion requires a longer proof, but not a difficult one, done by examining all cases.

Examining several sequences to aid in the formulation of the proofs given here led to an interesting question. If Brother Alfred's conjecture is not true for a whole sequence, can it be true for some elements of the sequence, and if so, which ones?
