# MODULO ONE UNIFORM DISTRIBUTION OF THE SEQUENCE OF LOGARITHMS OF CERTAIN RECURSIVE SEQUENCES 

J. L. BROWN, JR., and R. L. DUNCAN

The Pennsylvania State University, University Park, Pennsylvania

Let $\left\{x_{j}\right\}_{1}^{\infty}$ be a sequence of real numbers with corresponding fractional parts $\left\{\beta_{j}\right\}_{1}^{\infty}$, where $\beta_{j}=x_{j}-\left[x_{j}\right]$ and the bracket denotes the greatest integer function. For each $\mathrm{n} \geq 1$, we define the function $\mathrm{F}_{\mathrm{n}}$ on $[0,1]$ so that $\mathrm{F}_{\mathrm{n}}(\mathrm{x})$ is the number of those terms among $\beta_{1}, \cdots, \beta_{\mathrm{n}}$ whichlie in the interval $[0, x)$, divided by $n$. Then $\left\{x_{j}\right\}_{1}^{\infty}$ is said to be uniformly distributed modulo one iff $\mathrm{lim}_{\infty} \mathrm{F}_{\mathrm{n}}(\mathrm{x})=\mathrm{x}$ for all $\mathrm{x} \in[0,1]$. In other words, each interval of the form $[0, \mathrm{x})$ with $\mathrm{x} \in[0,1]$, contains asymptotically a proportion of the $\beta_{n}{ }^{\prime} \mathrm{s}$ equal to the length of the interval, and clearly the same will be true for any subinterval $(\alpha, \beta)$ of $[0,1]$. The classical Weyl criterion ( $[1], p .76$ ) states that $\left\{x_{j}\right\}_{1}^{\infty}$ is uniformly distributed mod 1 iff

$$
\begin{equation*}
\lim _{\mathrm{n} \rightarrow \infty} \frac{1}{\mathrm{n}} \sum_{\mathrm{j}=1}^{\mathrm{n}} \mathrm{e}^{2 \pi \mathrm{i} \nu \mathrm{x}_{\mathrm{j}}}=0 \quad \nu \geq 1 \tag{1}
\end{equation*}
$$

An example of a sequence which is uniformly distributed $\bmod 1$ is $\{n \xi\}_{n=0}^{\infty}$ where $\boldsymbol{\xi}$ is an arbitrary irrational number (see [1], p. 81 for a proof using Weyl's criterion).

The purpose of this paper is to show that the sequence $\left\{\ln \mathrm{V}_{\mathrm{n}}\right\}_{1}^{\infty}$ is uniformly distributed $\bmod 1$, where $\left\{\mathrm{V}_{\mathrm{n}}\right\}_{1}^{\infty}$ is defined by a linear recurrence of the form
(2)

$$
\mathrm{V}_{\mathrm{n}+\mathrm{k}}=\mathrm{a}_{\mathrm{k}-1} \mathrm{~V}_{\mathrm{n}+\mathrm{k}-1}+\cdots+\mathrm{a}_{0} \mathrm{~V}_{\mathrm{n}} \quad \mathrm{n} \geq 1
$$

the initial terms $V_{1}, V_{2}, \cdots, V_{k}$ being given positive numbers. In (2), we assume that the coefficients are non-negative rational numbers with $a_{0} \neq 0$, and that the associated polynomial $x^{k}-a_{k-1} x^{k-1}-\cdots-a_{1} x-a_{0}$, has roots $\beta_{1}, \beta_{2}, \cdots, \beta_{\mathrm{k}}$ which satisfy the inequality $0<\left|\beta_{1}\right|<\ldots<\left|\beta_{\mathrm{k}}\right|$. Additionally, we require that $\left|\beta_{j}\right| \neq 1$ for $j=1,2, \cdots, k$.

In particular, our result implies that any sequence $\left\{U_{n}\right\}_{1}^{\infty}$ which satisfies the Fibonacci recurrence $U_{n+2}=U_{n+1}+U_{n}$ for $n \geq 1$ with $U_{1}=k_{1}$ and $\mathrm{U}_{2}=\mathrm{k}_{2}$ arbitrary positive initial terms (not necessarily integers) will have the property that $\left\{\ln \mathrm{U}_{\mathrm{n}}\right\}_{1}^{\infty}$ is uniformly distributed mod 1. With $\mathrm{k}_{1}=$ 1 , $\mathrm{k}_{2}=1$, we obtain this conclusion for the classical Fibonacci sequence (see [2], Theorem 1), while for $k_{1}=1, k_{2}=3$, an analogous result is seen to hold for the Lucas sequence.

Before proving the main theorem, we prove two lemmas:
Lemma 1. If $\left\{x_{j}\right\}_{1}^{\infty}$ is uniformly distributed $\bmod 1$ and $\left\{y_{j}\right\}_{1}^{\infty}$ is such that $\lim _{j \rightarrow \infty}\left(x_{j}-y_{j}\right)=0$, then $\left\{y_{j}\right\}_{i}^{\infty}$ is uniformly distributed mod ${ }_{1}^{1}$.

Proof. From the hypothesis and the continuity of the exponential function, it follows that

$$
\lim _{j \rightarrow \infty}\left(e^{2 \pi i v x_{j}}-e^{2 \pi i \nu y_{j}}\right)=0
$$

But it is well known ([3], Theorem B, p. 202) that if $\left\{\gamma_{n}\right\}$ is a sequence of real numbers converging to a finite limit $L$, then

$$
\lim _{\mathrm{n} \rightarrow \infty} \frac{1}{\mathrm{n}} \sum_{1}^{\mathrm{n}} \gamma_{j}=\mathrm{L}
$$

Taking $\gamma_{j}=e^{2 \pi i \nu x_{j}}-e^{2 \pi i \nu y_{j}}$, we have

$$
\lim _{\mathrm{n} \rightarrow \infty} \frac{1}{\mathrm{n}} \sum_{\mathrm{j}=1}^{\mathrm{n}}\left(\mathrm{e}^{2 \pi \mathrm{i} \nu \mathrm{x}_{\mathrm{j}}}-\mathrm{e}^{\left.2 \pi \mathrm{i} \nu \mathrm{y}_{j}\right)=0}\right.
$$

Since

$$
\lim _{\mathrm{n} \rightarrow \infty} \frac{1}{\mathrm{n}} \sum_{1}^{\mathrm{n}} \mathrm{e}^{2 \pi \mathrm{i} \nu \mathrm{x}_{\mathrm{j}}}=0
$$

by Weyl's criterion, we also have

$$
\lim _{\mathrm{n} \rightarrow \infty} \frac{1}{\mathrm{n}} \sum_{1}^{\mathrm{n}} \mathrm{e}^{2 \pi \mathrm{i} \nu y_{j}}=0
$$

and the sufficiency of Weyl's criterion proves the sequence $\left\{y_{j}\right\}_{1}^{\infty}$ to be uniformly distributed mod 1.

Lemma 2. If $\alpha$ is a positive algebraic number not equal to one, then $\ln \alpha$ is irrational.

Proof. Assume, to the contrary, $\ln \alpha=(p / q)$, where $p$ and $q$ are non-zero integers. Then $e^{p / q}=\alpha$, so that $e^{p}=\alpha^{q}$. But $\alpha^{p}$ is algebraic, since the algebraic numbers are closed under multiplication ([1], p. 84). Thus $e^{p}$ is algebraic, in turn implying $e$ is algebraic. But $e$ is known to be transcendental ([1], p. 25) so that a contradiction is obtained.

Theorem. Let $\left\{\mathrm{V}_{\mathrm{n}}\right\}_{1}^{\infty}$ be a sequence generated by the recursion relation,
(2) $\quad \mathrm{V}_{\mathrm{n}+\mathrm{k}}=\mathrm{a}_{\mathrm{k}-1} \mathrm{~V}_{\mathrm{n}+\mathrm{k}-1}+\cdots+\mathrm{a}_{1} \mathrm{~V}_{\mathrm{n}+1}+\mathrm{a}_{0} \mathrm{~V}_{\mathrm{n}} \quad(\mathrm{n} \geq 1)$,
where $a_{0}, a_{1}, \cdots, a_{k-1}$ are non-negative rational coefficients with $a_{0} \neq 0$, $k$ is a fixed integer, and

$$
\begin{equation*}
\mathrm{V}_{1}=\gamma_{1}, \quad \mathrm{~V}_{2}=\gamma_{2}, \cdots, \quad \mathrm{~V}_{\mathrm{k}}=\gamma_{\mathrm{k}} \tag{3}
\end{equation*}
$$

are given positive values for the initial terms. Further, we assume that the polynomial $\mathrm{x}^{\mathrm{k}}-\mathrm{a}_{\mathrm{k}-1} \mathrm{x}^{\mathrm{k}-1}-\cdots-\mathrm{a}_{1} \mathrm{x}-\mathrm{a}_{0}$ has k distinct roots $\beta_{1}, \beta_{2}, \cdots$, $\beta_{\mathrm{k}}$ satisfying $0<\left|\beta_{1}\right|<\cdots<\left|\beta_{\mathrm{k}}\right|$ and such that none of the roots has magnitude equal to 1 . Then $\left\{\ln V_{n}\right\}_{1}^{\infty}$ is uniformly distributed mod 1.

Proof. The general solution of the recurrence (2) is

$$
\begin{equation*}
\mathrm{V}_{\mathrm{n}}=\sum_{\mathrm{j}=1}^{\mathrm{k}} \alpha_{\mathrm{j}} \beta_{\mathrm{j}}^{\mathrm{n}} \quad(\mathrm{n} \geq 1) \tag{4}
\end{equation*}
$$

where the arbitrary constants $\alpha_{1}, \alpha_{2}, \cdots, \alpha_{\mathrm{k}}$ are determined by the specification of the initial terms in (3). [It is easily checked that the determinant of the kxk matrix $\left(\beta_{\mathrm{j}}^{\mathrm{i}}\right)$ does not vanish, so that determination of the $\alpha_{j}^{\prime} \mathrm{s}$ is
unique.] Since the initial terms were not all zero, at least one of the $\alpha_{j}^{\prime}$ s is non-zero. Let $p$ be the largest value of $j$ for which $\alpha_{j} \neq 0$, so that $p \geq 1$. Then

$$
\mathrm{V}_{\mathrm{n}}=\sum_{1}^{\mathrm{p}} \alpha_{\mathrm{j}} \beta_{\mathrm{j}}^{\mathrm{n}}
$$

and

$$
\left|1-\frac{v_{n}}{\alpha_{p} \beta_{p}^{n}}\right|=\left|\sum_{1}^{p-1} \frac{\alpha_{j} \beta_{j}^{n}}{\alpha_{p} \beta_{p}^{n}}\right| \leq \sum_{1}^{p-1}\left|\frac{\alpha_{j}}{\alpha_{p}}\right|\left|\frac{\beta_{j}}{\beta_{p}}\right|^{n}
$$

But

$$
\left|\frac{\beta_{\mathrm{j}}}{\beta_{\mathrm{p}}}\right|<1
$$

for $j=1,2, \cdots, p-1$, and hence,

$$
\lim _{\mathrm{n}}\left(\frac{\mathrm{v}_{\mathrm{n}}}{\left|\alpha_{\mathrm{p}} \beta_{\mathrm{p}}\right|}\right)=1
$$

or equivalently,

$$
\begin{equation*}
\lim _{\mathrm{n} \rightarrow \infty}\left[\ln V_{\mathrm{n}}-\ln \left|\alpha_{\mathrm{p}} \beta_{\mathrm{p}}\right|^{\mathrm{n}}\right]=0 \tag{5}
\end{equation*}
$$

Since $\beta_{p}$ is algebraic, it is easily verified that $\left|\beta_{p}\right|$ is also algebraic. Moreover, $\left|\beta_{p}\right| \neq 1$ by hypothesis so that $\ln \left|\beta_{p}\right|$ is irrational by application of Lemma 2. But the sequence $\{n \xi\}_{1}^{\infty}$ is uniformly distributed mod 1 whenever $\xi$ is irrational; therefore, the sequence

$$
\left\{n \ln \left|\beta_{p}\right|\right\}_{1}^{\infty}=\left\{\ln \left|\beta_{p}\right|^{n}\right\}_{1}^{\infty}
$$

is uniformly distributed mod 1 and the same is true for the sequence

$$
\left\{\ln \left|\alpha_{p}\right|\left|\beta_{p}\right|^{n}\right\}_{i}^{\infty}
$$

From (5) and Lemma 1, it is then clear that $\left\{\ln \mathrm{V}_{\mathrm{n}}\right\}_{1}^{\infty}$ is uniformly distributed $\bmod 1$ as asserted. q.e.d.

The specialization to sequences satisfying the Fibonacci recurrence, $\mathrm{U}_{\mathrm{n}+2}=\mathrm{U}_{\mathrm{n}+1}+\mathrm{U}_{\mathrm{n}}(\mathrm{n} \geq 1)$, is immediate since the relevant polynomial in this case is $x^{2}-x-1$, and there are two distinct roots of unequal magnitude, namely

$$
\frac{1 \pm \sqrt{5}}{2} .
$$

From the theorem, we conclude $\left\{\ln \mathrm{U}_{\mathrm{n}}\right\}_{1}^{\infty}$ is uniformly distributed mod 1 independently of the (non-zero) values specified for $U_{1}$ and $U_{2}$.

Lastly, we give an example to show that our assumption on the roots of the associated polynomial cannot be relaxed. Consider the recurrence $\mathrm{V}_{\mathrm{n}+2}$ $=\mathrm{V}_{\mathrm{n}}$ for $\mathrm{n} \geq 1$ with $\mathrm{V}_{1}=1, \mathrm{~V}_{2}=1$. Then clearly $\mathrm{V}_{\mathrm{n}}=1$ for all $\mathrm{n} \geq 1$ so that $\left\{\ln V_{n}\right\}_{1}^{\infty}$ is a sequence of zeroes and hence not uniformly distributed mod 1. The associated polynomial in this case is $x^{2}-1$ which has two distinct roots, $\pm 1$; however, the roots have magnitude unity, and therefore, the conditions of our theorem are not met.
